Table of Contents

I. Introduction	26
II. Executive Summary.....	30
Chapter 1: The Macro level: Digital competition – Technology and Business Environment	49
1.1. Introduction	49
1.1.1. The Main Challenge of Our Digital Future	49
1.1.2. A Mechanistic Trap of Modern Competition Law	53
1.1.3. Competition Law for the Fluid Modernity	56
1.1.4. Global Nature of Competition Regulation	59
1.1.5. The emergence of digital financial capitalism	62
1.1.6. Case study: Fintech and banks in the Digital era	63
1.2. Consequences of digital competition for economic actors and the intangible economy: empirical insights	77
1.2.1. Country-level effects.....	77
1.2.2. Region-level effects: BRICS.....	79
1.2.3. Consumer-level effects.....	81
1.3. The new global digital eco-system and BRICS: a political economy perspective on the relation between industrial policy and competition law and policy	84
1.3.1. Industrial policy and digital transformation: an overview.....	84
1.3.2. Framework of digital strategies	86
1.3.3. Degree of prudence in introducing regulation.....	88
1.3.4. Providing internet access.....	89
1.3.5. Data sovereignty	91
1.3.6. Protectionist aspects of digital policy	92
1.3.7. Role of the competition authority	94
1.3.8. Mergers	95
1.3.9. Investigations of competition law violations	96
1.4. Digital trade and markets: an international governance perspective	102
1.4.1. General context of digital trade	102
1.4.2. Inter-jurisdictional data transfers: an overview	104
1.4.3. International regulation of the digital economy	105

1.4.3.1. Regulation of cross-border data flows.....	105
1.4.3.1.1. Data protection	105
1.4.3.1.1.1. Economic regulation.....	109
1.4.3.2. International regulation of digital consumer protection.....	113
1.4.4. Prospects for the future: global digital regulation and competition policy	114
1.5. A brief description of digital technologies	115
1.5.1. Artificial Intelligence.....	115
1.5.2. Machine Learning	118
1.5.3. Big Data	120
1.5.4. Smart Data	123
1.5.5. Blockchain.....	125
Chapter 2: Economics of Platforms	128
2.1. Theories of harm for multisided platforms: challenges for competition policy and BRICS answers	128
2.1.1. Multisided platforms: increasing attention of competition policy	128
2.1.2. Implications of the economic theory of MSP for competition policy	132
2.1.2.1. Incentives to enter and market structure of MSP	132
2.1.2.2. Impact of network externalities on the effectiveness of exclusionary contracts ..	133
2.1.2.3. Justifications of exclusionary conduct	135
2.1.2.4. Unresolved and problematic issues in competition policy towards MSPs	136
2.1.3. Competition policy towards multisided markets in BRICS	139
2.1.3.1. Market definition and multisided markets	139
2.1.3.2. Theories of harm	140
2.1.3.2.1. Exclusionary conduct through vertical foreclosure.....	140
2.1.3.2.2. Exclusionary conduct through other forms of competition softening	140
2.1.3.2.3. Exploitative conduct in a value chain perspective	141
2.1.3.3. Efficiencies and multisided markets.....	143
2.1.3.4. Competition remedies	144
2.1.3.4.1. Remedies promoting interplatform competition	144
2.1.3.4.2. Remedies promoting intraplatform competition	145
2.1.3.4.3. Other remedies	145
2.1.4. Conclusion	146

2.2. Theories of harm for multi-sided platforms II: practical implications for BRICS competition policy	147
2.2.1. Issues to be resolved under antitrust analysis of MSPs	148
2.2.1.1. To decide whether the MSP concept is necessary	148
2.2.1.2. The need to identify the type of the MSP and approaches to market delineation	149
2.2.1.3. The need to identify and test abusive intent	151
2.2.1.4. The need to choose tests for potential consumer harm in mergers and dynamic competition	153
2.2.2. Delimiting markets and measuring market power in two-sided markets: the role of demand functions.	155
2.2.2.1. Critical Loss analysis, SSNIP and HM test.....	157
2.2.2.2. Estimation of market shares, concentration and dominance	161
2.2.2.3. Modified GUPPI to unilateral effects assessment	162
2.2.2.4. Tests for exclusionary abuses in MSP.....	164
2.2.2.5. Tests for efficiency effects.....	166
2.2.3. Conclusion	167
Chapter 3: The Private governance of Digital Value Chains	170
3.1. Introduction	170
3.2. A 'Natural order' rhetoric to the private governance of platforms and ecosystems?.....	170
3.2.1. Transaction cost economics and private governance	171
3.2.2. Resource based theory of the firm and GVC approaches	173
3.2.2.1. Emergence of the GVC framework	176
3.2.2.2. Dual Role of Private Governance in the GVC framework	178
3.2.2.3. Explanatory Potential of the GVC approach	180
3.2.2.4. Defining the right unit of analysis for public policy purposes: Digital Value Chains, Platforms, Ecosystems	181
3.3. Challenging the 'natural order' explanation: the regulating role of digital platforms	183
3.4. A Typology of private governance systems: a theoretical perspective.....	187
3.5. Beyond the 'natural order' rhetoric: a (legal/technology) institutional perspective	189
3.5.1. Contractual governance – Legal institutionalism	189
3.5.2. Contract automation under big data: The “uncontract” (<i>Zuboff</i>)	192
3.6. Drawing on the empirical evidence: a bestiary of governance tools in digital platforms and ecosystems.....	194

3.6.1. Patterns of governance in P2B relations	194
3.6.1.1. Translating business models into governance patterns	194
3.6.1.2. Interplay between contractual, soft and technological layers of governance.....	196
3.6.1.3. Relevant terms: Data transferability, price-setting, suspension of service/member- ship	196
3.6.2. Patterns of governance in P2C relations	197
3.6.2.1. Translating business models into governance patterns	197
3.6.2.2. Interplay between contractual, soft and technological layers of governance.....	198
3.6.2.3. Relevant terms: Legal qualification of the agreement, privacy, and liability	198
3.6.3. Conclusions: Linking of P2C and P2B governance as characteristic of multi-sided mar- kets	200
Chapter 4: General Conceptual Framework	202
4.1. A complex economy perspective for digital competition law.....	202
4.1.1. Competition law in liminal times: beyond neoclassical price theory	202
4.1.2. What are the distinctive characteristics of a complex economy perspective?.....	205
4.2. Is the consumer welfare standard adequate to deal with the competition challenges of digital competition, and how could this consumer welfare standard be defined?.....	210
4.2.1. The pitfalls of the consumer welfare standard in a complex digital economy	210
4.2.2. Should competition law take into account the broader social cost of restriction of compe- tition in the digital economy, and can this be done?	220
4.2.2.1. Income and wealth distribution	221
4.2.2.2. Privacy.....	224
4.2.2.3. Fairness and complex equality	227
4.3. The changing competition game.....	229
4.3.1. Financialisation and the re-interpretation of competition: implications for the digital economy.....	230
4.3.1.1. Financialisation and the rise of financial capitalism: implications for the digital econ- omy and competition	231
4.3.1.2. Digital platforms and financialisation	239
4.3.1.2.1. Shareholdings of Digital Platforms.....	240
4.3.1.2.2. Shareholder Voting Rights	245
4.3.1.2.3. Dividends, Share Buybacks and Investment	246
4.3.1.3. Futurity and the financial dimension of competition in the digital economy.....	249

4.3.2. Competitive advantage beyond horizontal competition	252
4.3.3. Vertical competition: introducing the concept.....	255
4.4. Moving beyond traditional relevant markets	267
4.4.1. Multi-sided markets and ‘transaction platforms’	268
4.4.2. From ‘Big’ and ‘Smart’ Data and ‘matching’ platforms to prediction platforms	272
4.4.2.1. Data and Big/Smart Data markets	272
4.4.2.2. Attention markets	277
4.4.3. Personalised markets.....	292
4.4.4. Ecosystems	300
4.4.5. The behavioural dimension: Market failures at the demand side.....	301
4.5. Moving beyond traditional definitions of market power	309
4.5.1. Conceptualizing power in the digital economy: a theoretical perspective.....	311
4.5.2. Is the traditional concept of horizontal market power fit for purpose in the digital economy?	314
4.5.2.1. Selling power	315
4.5.2.2. Buyer power and monopsony	316
4.5.2.3. Can existing market power concepts take into account innovation effects?	318
4.5.3. Vertical non-structural power: variations on a theme	322
4.5.3.1. Bottleneck or chokepoints power	322
4.5.3.2. ‘Intermediation’ power	324
4.5.3.3. Superior bargaining power	327
4.5.3.4. Panopticon power	337
4.5.3.5. Architectural power	338
4.6. Digital value chains as a new mapping tool in competition law: concept and metrics	342
4.6.1. Digital Value Chains as a new mapping tool	343
4.6.2. Vertical power: metrics	352
4.7. A roadmap for the future.....	354
Chapter 5: The scope of competition law in the digital economy.....	363
5.1. Introduction	363
5.2. Adjusting the scope of competition law	364
5.2.1. The personal scope of competition law in the digital economy	364
5.2.1.1. Labour and Competition Law in the Digital Economy	365

5.2.1.1.1. Defining the problem	365
5.2.1.1.2. Re-inventing new legal categories?.....	377
5.2.1.2. Promoting Collective Bargaining for labour and beyond (users)	384
5.2.1.3. Designing competition law for the digital labour market	388
5.2.1.4. Competition law and blockchain technology: defining economic activity and regulat- ability issues	395
5.2.2. The material scope of competition law: filling the jurisdictional gaps of merger control	400
5.2.3. The geographic scope of substantive competition law and remedies.....	402
5.3. The interaction of competition law with other legal fields in the digital economy: a separate fields approach or a regime of mutual reinforcement?	407
5.4. Re-designing competition law remedies and procedures for the digital economy	410
5.4.1. Rapidity of enforcement action: interim measures in order to ensure the effectiveness of enforcement in the digital era	410
5.4.1.1. Interim Measures and Commitment Decisions in EU Competition Law and Practice	411
5.4.1.1.1. Interim measures	411
5.4.1.1.2. Consent orders (commitment decisions).....	413
5.4.1.2. Interim measures and Negotiated Settlement (Commitment) in US Antitrust Law and Practice.....	414
5.4.1.2.1. Interim measures	414
5.4.1.2.2. Negotiated settlements (commitments)	416
5.4.1.3. Interim Measures and Commitment Decisions in BRICS Countries Competition Law and Practice	417
5.4.1.3.1. Interim measures.....	417
5.4.1.3.2. Commitments Decisions	420
5.4.2. Towards a different model of competition law remedies	422
5.4.2.1. Competition law remedies for a complex economy.....	422
5.4.2.2. The use of structural remedies and break ups: the past as present.....	427
5.4.2.3. Preventive structural adjudication	438
5.4.2.4. Ex ante or ex post regulation of algorithms	440
5.4.2.5. Data portability.....	440
5.4.2.5.1. Data Portability in EU Regulations	441
5.4.2.5.2. Data Portability in the US.....	443

5.4.2.5.3. Data Portability in the BRICS Countries	444
5.4.2.6. Data commons or data clubs and interoperability	450
5.4.2.7. Self-regulation and Codes of conduct on the basis of competition law principles.....	455
5.4.2.8. Competition by design.....	456
5.5. Enforcement statistics – digital antitrust in BRICS countries	457
5.5.1. Aggregate BRICS.....	458
5.5.1.1. Aggregate BRICS mergers	458
5.5.1.2. Aggregate BRICS infringements	459
5.5.2. Brazil.....	462
5.5.2.1. Brazil mergers	462
5.5.2.2. Brazil infringements	463
5.5.3. South Africa	465
5.5.3.1. South Africa mergers	465
5.5.3.2. South Africa infringements	466
5.5.4. Russia	469
5.5.4.1. Russia mergers	469
5.5.4.2. Russia infringements	470
5.5.5. India.....	472
5.5.5.1. India mergers.....	472
5.5.5.2. India infringements	473
5.5.6. China	476
5.5.6.1. China mergers	476
5.5.6.2. China infringements	477
Chapter 6: E-commerce, competition law and digital vertical restraints.....	480
6.1. General discussion.....	480
6.1.1. The growth of e-commerce and digital vertical supply management	483
6.1.2. How do changes in technology affect the types of vertical restraints adopted?.....	487
6.1.3. What are the recent changes in business methods observed?	489
6.2. Foundations for the competition assessment of online vertical restraints	490
6.2.1. Are online vertical restraints different from offline vertical restraints?	490
6.2.2. Platform governance and commercial agency immunity.....	492
6.2.3. Online distribution of content and competition law	500

6.3. A bestiary of online vertical restraints: a comparative perspective.....	504
6.3.1. Restrictions on sales.....	504
6.3.1.1. Geo-blocking and geo-filtering	504
6.3.1.2. Online sale bans and platform bans and restrictions	507
6.3.2. Price discrimination and targeting	511
6.3.3. Across Platform Parity Agreements (APPAs)	512
6.3.4. Online RPM or RPM facilitating conduct	522
6.3.5. Dual distribution and dual role (platform/retail) of online platforms.....	532
6.3.6. 'Enveloping' and bundling strategies.....	539
6.4. Conclusions.....	539
Chapter 7. Exclusionary and unfair unilateral practices in reference to Platforms	546
7.1. Introduction	546
7.2. Dominance Based on Control and Access to Ecosystems	550
7.2.1. Controlling ecosystem and networks equals power under competition Law?	550
7.2.2. What is data?	557
7.2.3. The blurring of data and physical: Data and the Internet of Things (IoT).....	559
7.2.5. Unique Data Sets and Competition Law	561
7.2.6. The Governance of Cloud and Market Power	562
7.3. Different forms of Abuses in reference to Data	565
7.3.1. What may be considered as abuse in a digital economy?	565
7.3.2. Refusing or obstructing access to data/algorithms or interoperability	567
7.3.2.1. A US perspective on access to data and interoperability	569
7.3.2.2. An EU perspective on access to data and interoperability.....	571
7.3.2.3. A BRICS perspective	576
7.3.3. (Exclusionary) Discrimination in providing data and search/algorithmic access and net neutrality	579
7.3.3.1. The many faces of discrimination in competition law	579
7.3.3.2. In-depth EU Perspective on the Google shopping case and Net Neutrality	584
7.3.3.3. BRICS.....	590
7.3.4. Leveraging and Enveloping	594
7.3.4.1. An economic perspective on leveraging and enveloping.....	594
7.3.4.2. EU and US: comparative perspectives	597

7.3.4.3. BRICS.....	600
7.3.5. Tying & bundling practices	604
7.3.5.1. An economic perspective on tying/bundling in the digital context.....	604
7.3.5.2. The tying/bundling competition law standards in the EU and the US.....	605
7.3.5.3. BRICS.....	607
7.3.6 Unfair commercial terms and lock-ins	610
7.3.6.1. Contractual or technical lock-ins	610
7.3.6.2. Nonassertion and Nonchallenge Clauses	613
7.3.6.3 Exploitative price discrimination	615
7.3.7. Harm to innovation	615
7.4. Comparative Analysis of Unilateral Exclusionary and Unfair Practices in Data Markets: EU, U.S. and BRICS	617
Chapter 8: Algorithmic Collusion and Competition Law	626
8.1. Can computers/algorithms collude or facilitate collusion?: setting the parameters of the problem.....	626
8.2. An Economic Perspective on tacit collusion and pricing algorithms	630
8.2.1. Can Algorithms Collude or Facilitate and Maintain Collusion?	632
8.2.1.1. Can Algorithms Facilitate Explicit Agreements?	632
8.2.1.2. Can algorithms result in tacit coordination?	633
8.2.1.3. Can algorithms facilitate tacit collusion?	634
8.2.2. Models of Algorithmic Collusion – Can algorithms collude?	636
8.2.3. Conditions in which Algorithmic (tacit/explicit) Collusion may successfully happen	639
8.3. A Legal Perspective: is the current antitrust law fit for purpose?	640
8.3.1. Communications-based v. effects-based approaches in defining collusion	640
8.3.2. Conceptual and technological limits of the communications-based approach.....	655
8.3.3. Is the antitrust concept of collusion and its emphasis on communication sufficient to take into account all forms of algorithmic collusion?	661
8.3.4. Reforming the antitrust concept of collusion.....	663
8.3.5. Concluding remarks: Policy options	664
8.4. Blockchain and Collusion	666
8.5. Algorithms: impact on cartel detection, leniency and competition law enforcement against cartels.....	671
8.5.1. Implications for leniency policies and detection tools for cartel activity.....	672

8.5.2. Algorithmic cartel detection	672
8.5.2.1. Cartel screening: old style	672
8.5.2.2. Cartel screening: existing software tools	673
8.5.2.3. Avenues for future development of software screening	679
8.5.2.4. The rise of Auction Robots in Electronic Procurement.....	680
8.5.3. Blockchain and detection of collusion	685
8.6. Conclusion.....	685
Chapter 9 : Digital Mergers : The Basics	687
9.1. Introduction	687
9.2. The Basic Principles of Merger Control	688
9.2.1. Horizontal Overlap and Unilateral Effects	689
9.2.2. Facilitation of Coordinated Effects.....	691
9.2.3. Facilitation of Abuse of Dominance.....	691
9.2.4. Innovation/Quality	692
9.2.5. Efficiencies	692
9.3. What does 'Digital' Mean and What does this Imply?.....	692
9.4. Main 'Digital' Merger Cases: a panorama of the legal issues.....	697
9.4.1. Market definition	697
9.4.1.1. The EU/US practice on market definition for digital mergers.....	698
9.4.1.2. A BRICS perspective	703
9.4.2. Theories of harm	706
9.4.2.1. Traditional theories of harm resulting from horizontal overlaps and elimination of direct competition	706
9.4.2.2. Preventing potential/nascent competition theories of harm	711
9.4.2.3. Vertical theories of harm: Foreclosure	715
9.4.2.4. Conglomerate theories of harm: big data and diversity of data as an important barrier to entry reinforcing concentration	722
9.4.2.5. Other vertical/conglomerate theories of harm: panopticon power	724
9.4.2.6. Innovation theories of harm	727
9.4.3. The challenges of a more dynamic assessment of mergers: Counterfactuals, standard of proof, burden of proof	731
9.5. Economics of digital mergers: a selection of topics.....	734
9.5.1. Market Definition	735

9.5.1.1. The Geographic Dimension.....	735
9.5.1.2. Individualised Pricing	736
9.5.2. Unilateral Horizontal Effects.....	738
9.5.2.1. Individualised Pricing and Consumer Targeting.....	738
9.5.2.2. Advertising	743
9.5.2.3. Data	743
9.5.3. Efficiencies	746
9.5.4. Innovation.....	747
9.5.5. Tacit Collusion	748
9.5.6. Conglomerate Mergers	750
9.5.7. Incentives to Abuse a Dominant Position and Merger Control	751
9.5.7.1. Dominance in Digital Sectors.....	752
9.5.7.2. Privileged Remedies: Interoperability and Data Sharing	753
9.5.7.3. Abuse of Dominance: Detection and Remedies.....	754
9.6. Conclusion and recommendations.....	756
Chapter 10: Case Study: Standard setting, Internet of Things and Industry 4.0.	758
10.1. Introduction	758
10.2. Introduction to IoT and Industry 4.0.....	758
10.2.1. Level of Development of IIoT	760
10.2.1.1. India	761
10.2.1.2. China.....	762
10.2.1.3. Russia.....	764
10.2.1.4. Brazil	767
10.2.1.5. South Africa.....	769
10.2.2. Areas in which IoT and Industry 5.0 are deployed	770
10.2.2.1. Terminal devices	770
10.2.2.2. Communication Infrastructure.....	771
10.2.2.3. Cloud Infrastructure	772
10.3. Estimating the future IoT and 5G patent landscape	773
10.3.1. IoT standards and patent landscape	773
10.3.2. 5G patent landscape	775
10.4. What types of standards are to the greatest extent covered by patents?.....	777

10.5. Different layers of standards, Infrastructure or lower layer interoperability, upper layer data interoperability	781
10.6. Distinguishing between open source versus proprietary models/ecosystems: the crucial role of interoperability.....	784
10.7. Connectivity (interoperability) standards.....	785
10.7.1. The notion and controversy surrounding Standard Essential Patents	786
10.7.2. The meaning of FRAND commitment to license Standard Essential Patents	787
10.7.2.1. The nature on FRAND: the interplay between contract, patent and competition law.....	788
10.7.2.2. FRAND Royalty Principles	791
10.7.2.3. A FRAND royalty base: Smallest Saleable Patent Practicing Unit (SSPPU) or end product?	793
10.7.3. Potential unilateral anticompetitive practices with respect to SEPs	795
10.7.3.1. Injunctions and standard essential patents	795
10.7.3.2. Refusal to license to upstream competitors (chip level licensing)	801
10.7.3.3. Excessive non-FRAND royalties	803
10.7.4. Comparative analysis of unilateral exclusionary and exploitative practices relating to IoT and standards: a BRICS' perspective.....	805
10.7.4.1. Injunctions	805
10.7.4.1.1. Brazil.....	805
10.7.4.1.2. Russia	806
10.7.4.1.3. India.....	806
10.7.4.1.4. China	806
10.7.4.2. The Determination of FRAND Royalty	809
10.7.4.2.1. Brazil.....	809
10.7.4.2.2. Russia	809
10.7.4.2.3. India.....	810
10.7.4.2.3.1. Methodology to calculate SEP royalty	810
10.7.4.2.3.2. CCI's Jurisdiction to review FRAND violations	815
10.7.4.2.4. China	816
10.7.4.2.4.1. Huawei v InterDigital case.....	816
10.7.4.2.4.2. Qualcomm case.....	818
10.7.4.2.4.3. The IP Guidelines.....	819

10.8. Upper layer standards – standards for data.....	819
10.8.1. Access to data issues.....	819
10.8.1.1. The role of competition law in providing access to data.....	821
10.8.1.2. Sectoral measures.....	825
10.8.2. Data pools.....	827
10.9. Other means for creating more competition?.....	829
10.9.1. Property solution.....	829
10.9.2. Access solution.....	831
10.9.3. Technological solutions: blockchain based IoT and Industry 4.0.	836
10.10. Conclusions.....	839
Chapter 11: Privacy Restrictions as Restrictions of Competition	840
11.1. Introduction	840
11.2. Privacy and Market Failures.....	846
11.2.1. Market failures through exclusionary and exploitative requirement contracts bundling digital services with personal data.....	847
11.2.2. Natural monopoly or natural oligopoly and market failure in privacy	856
11.2.2. Lock in and Hold up.....	860
11.2.3. Information asymmetries and information related failures	861
11.2.4. Missing markets.....	862
11.3. Exploitative and exclusionary conduct involving privacy-related theories of harm: ex ante and ex post enforcement	863
11.3.1. Ex ante enforcement: data mergers and privacy	864
11.3.2. Ex post enforcement: abuse of a dominant position or economic dependence	869
11.3.2.1. Excessive data extraction	869
11.3.2.2. Personalised pricing.....	880
11.3.2.3. Unfair commercial practices and trading conditions	885
11.3.2.4. Exploitative requirement contracts	900
11.3.2.5. Behavioural manipulation	900
11.4. Conclusion and Remedies.....	906
Chapter 12: Country Report – Brazil	911
12.1. Introduction	911
12.2. Industry and technological background.....	911
12.2.1 Internet access penetration levels in Brazil.....	912

12.2.2. Digital Economy Growth: smart cities, Internet of Things, and the corporate finance for the digital economy.	917
12.2.3. How many consumers are actively engaging in e-commerce?	921
12.2.4. Engagement with social networks.....	921
12.2.5. Affordability of connectivity	923
12.2.6. Industry structure: concentration levels in your jurisdiction (if available) for: (a) internet access providers; (b) search engines; (c) search networks; (d) online advertising; (e) cloud computing.....	923
12.3. Institutional framework for the digital economy in brazil	926
12.3.1. Digital consumer protection framework	926
12.3.2 What is protected by property rights?	928
12.3.3 Privacy/Data Protection Regulation.....	930
12.3.4 Institutional Architecture	932
12.4. Conclusion	949
Chapter 13: Country Report – Russia*	951
13.1.What is the Business/Technological Environment for the digital economy in your jurisdiction?.....	951
13.1.1. What is the Internet access penetration level in your jurisdiction as part of the total population?	951
13.1.2. Digital Economy Growth levels in your jurisdiction the last 5 years	956
13.1.3. How many consumers are actively engaging in e-commerce?.....	961
13.1.4. Engagement with social networks	964
13.1.5. Level of development of the IoT and Industry 4.0. in your jurisdiction	965
13.1.6. Please specify the major digital platforms in your jurisdiction and their market penetration.	967
13.1.7. Local large digital players and their market shares	971
13.2. What is the institutional framework for the digital economy in your jurisdiction?	973
13.2.1. Is there a digital strategy agenda in your jurisdiction? How this (if at all) relates to competition law and policy and what is the level of involvement of the competition authority (or authorities)?	973
13.2.2. What is protected by property rights (rights to exclude, transfer and monetise)?	975
13.2.3. Succinctly present the current regulatory framework in your jurisdiction	982
13.2.4. Institutional architecture	989
13.2.5. Describe the competition law activity of your jurisdiction related to the digital economy	

since 2001	999
13.2.6. Recent and Ongoing Reforms of the Competition Law as the Result of Digitization	1008
Chapter 14: Country Report – India	1016
14.1. What is the Business/Technological Environment for the digital economy in your jurisdiction?	1016
14.1.1. What is the Internet access penetration level in your jurisdiction as part of the total population?	1016
14.1.2. Composition of Internet users (age, gender, rural v. cities)	1016
14.1.3. Availability of Internet networks	1017
14.2. Digital Economy Growth levels in your jurisdiction the last 5 years	1020
14.2.1. Smart cities and networks development.....	1020
14.2.2. Corporate finance for the digital economy	1020
14.2.3. How many consumers are actively engaging in e-commerce?	1021
14.2.4. Engagement with social networks	1021
14.2.4.1 Most popular social networks in your jurisdiction.....	1021
14.2.4.2. Do consumers practice single-homing or multi-homing regarding social networks?	1021
14.2.5. Level of development of the IoT and Industry 4.0. in your jurisdiction	1021
14.2.6. Please specify the major digital platforms in your jurisdiction and their market penetration.	1022
14.2.6.1. Concentration levels in your jurisdiction (if available) for:.....	1022
14.2.7. Information about ownership (foreign or domestic, state-owned versus private)...	1022
14.2.8. Please indicate any local large digital players and their market shares.....	1023
14.2.9. What is the level of development of the blockchain economy in your jurisdiction?	1024
14.3. What is the institutional framework for the digital economy in your jurisdiction?	1025
14.3.1. An overview of regulatory and policy frameworks relevant for digital economy.....	1025
14.3.1.1. The Information Technology Act 2000	1025
14.3.1.2. Draft Personal Data Protection Bill 2018	1030
14.3.1.3. RBI Notification on Storage of Payment System Data 2018	1040
14.3.1.4. Press Note 2 of 2018 (FDI Rules on e-commerce).....	1040
14.3.1.5. Draft National e-Commerce Policy 2019.....	1042
14.3.1.6. Draft e-Pharmacy Rules 2018	1047
14.3.1.7. Draft Digital Information Security in Healthcare Act 2017	1048

14.3.1.8. The National Digital Communication Policy	1051
14.3.2. Is there a digital strategy agenda in your jurisdiction? How this (if at all) relates to competition law and policy and what is the level of involvement of the competition authority (or authorities)?	1053
14.3.3. What is protected by property rights (rights to exclude, transfer and monetise)? ..	1056
14.3.3.1. Intellectual property rights (IPRs) in the digital economy	1056
14.3.3.2. Are there any other property rights over data? Are data/algorithms subject to sui generis property rights?	1058
14.3.3.3. Rights of control and portability on personal data?	1058
14.3.4. Specific regulatory regimes	1059
14.3.4.1. Electronic communications.....	1059
14.3.4.2. Access to Data	1060
Chapter 15: Country Report – China	1070
15.1 The Business and Technological Environment for the Digital Economy of China	1070
15.1.1 Internet Access and Use in China	1070
15.1.1.1 Internet User Size and Its Structure Distribution in China.....	1070
15.1.1.1.1 Internet User Size in China	1070
15.1.1.1.3 Gender Structure of Chinese Internet Users.....	1071
15.1.1.1.4 Urban-rural Distribution Structure of Chinese Internet Users	1072
15.1.1.2 Availability of China's Internet Network	1072
15.1.1.2.1 China Internet Network Coverage.....	1072
15.1.1.2.2 Network Operators Available to Chinese Consumers	1073
15.1.1.2.3 The Ownership of and Regulation over Chinese Network Operators	1074
15.1.1.2.4 Affordability of China's Internet Network	1075
15.1.1.2.5 China Internet Access Service	1076
15.1.2 Overview of China's Digital Economy Development	1078
15.1.2.1 Overall Situation of China's Digital Economy Development	1078
15.1.2.2 Construction and Development of China's Smart Cities	1079
15.1.2.3 Main Financing Channels for Chinese Digital Economy Enterprises	1080
15.1.3 Overview of China's E-commerce Development.....	1081
15.1.4 Overview of China's Social Network Development	1082
15.1.4.1 The Main Social Networking Platform Currently Popular in China.....	1082
15.1.4.2 User Aggregation and Homing of Social Network Platforms.....	1084

15.1.5 Overview of China's Internet of Things and Industry 4.0 Development	1085
15.1.5.1 Status Quo of China's IoT Development.....	1085
15.1.5.2 China Industry 4.0 – “Made in China 2025”	1087
15.1.6 Market Penetration of China's Digital Platforms and their Ownership	1088
15.1.6.1 The Concentration of Internet Access Providers and their Ownership Profiles	1088
15.1.6.2 The Market Concentration of Search Engine Platforms and their Ownership Profiles ...	1089
15.1.6.3 The Concentration of Social Networking Platforms and their Ownership Profiles	1090
15.1.6.4 The Concentration of Internet Advertisers and their Ownership Profile	1091
15.1.6.5 the Concentration of Cloud Computing Platforms and their Ownership Profiles	1093
15.2 The Institutional Framework of China's Digital Economy	1095
15.2.1. China's Digital Economy Development and Its Relationship with Competition Law.	1095
15.2.1.1 China's Digital Economy Development Process	1095
15.2.1.2 China's Digital Economy Development Strategy	1096
15.2.1.2.1 China's Strategy of Information Technology and E-commerce Development ...	1096
15.2.1.2.2 China's “Internet Plus” Action	1097
15.2.1.2.3 China's Big Data Development Strategy	1097
15.2.1.3 China's Digital Economy Strategy and its Relationship with Competition Policy	1098
15.2.1.3.1 China's Digital Economic Policy and Competition Policy	1098
15.2.1.3.2 The Role of Anti-monopoly Law Enforcement Agencies in the Digital Economy Strategy.....	1099
15.2.2. Digital Property Protection in the Perspective of Chinese Law	1099
15.2.2.1 Intellectual Property Issues in the Digital Economy	1099
15.2.2.1.1 Intellectual Property and Big Data	1099
15.2.2.1.2 Intellectual Property Issues in the Field of Artificial Intelligence	1100
15.2.2.1.3 Other Intellectual Property Issues.....	1101
15.2.2.2 Propertilization of Industrial Data and Algorithms	1102
15.2.2.3 Propertilization of Personal Data and Protection of Personal Information	1103
15.2.2.4 The Regulatory System Involving Digital Property	1106
15.2.3. Digital Economy Management System in the Perspective of Chinese Law.....	1106

15.2.3.1 The Regulatory System of the Telecommunications Industry.....	1106
15.2.3.1.1 Telecommunications Regulation Authority.....	1107
15.2.3.1.2 Telecommunications Licensing System.....	1108
15.2.3.1.3 Internet Regulation.....	1109
15.2.3.2 Industry Regulation of Big Data.....	1110
15.2.3.3 Consumer Protection in the Field of the Digital Economy.....	1111
15.2.3.3.1 Protection of Digital Economy Consumers in the Law on Protection of the Rights and Interests of Consumers.....	1111
15.2.3.3.2 The Protection of Digital Economy Consumers in the E-Commerce Law...	1112
15.2.3.4 Regulatory Protection of Personal Information.....	1113
15.2.4. Regulatory Authorities and their Structures in the Field of China's Digital Economy	1114
15.2.4.1 Functional Departments of China's Digital Economy Regulation.....	1114
15.2.4.2 The Role of Competition Law Enforcement Agencies in the Development of the Digital Economy.....	1114
15.2.4.3 The Role of the People's Courts in the Development of the Digital Economy....	1115
15.2.5. The Relationship between Competition Law Enforcement and Industry Regulation in the Field of the Digital Economy.....	1117
15.2.5.1 Interaction between Competition Law Enforcement Agencies and Industry Regulatory Authorities.....	1117
15.2.5.1.1 Joint Enforcement Mechanism of Anti-monopoly Law Enforcement Agencies and Industry Regulatory Authorities.....	1117
15.2.5.1.2 Implementation of the Fair Competition Review System.....	1118
15.2.5.2 Relationship between Competition Law Enforcement Agencies and Consumer Protection Agencies.....	1118
15.2.5.3 The Relationship between Competition Law Enforcement Agencies and Specialized Intellectual Property Agency.....	1119
15.2.5.4 Anti-monopoly Exemptions for Specific Industries.....	1120
15.2.6. A Brief Introduction on the Implementation of the Competition Law in China's Digital Economy (cases, compilations, etc.).....	1121
15.2.7. Amendments of China's Competition Law and Reform of Regulatory Agencies.....	1121
15.2.7.1 Amendment of China's Law against Unfair Competition and its Coordination with the Anti-monopoly Law.....	1121
15.2.7.2 Tendency of Revision of China's Anti-monopoly Law.....	1122
15.2.7.3 Impact of China's State Institutional Reform on the Implementation of Competition Law.....	1123

15.2.7.3.1 The Powers of China's Anti-monopoly Law Enforcement Agencies before the Reform	1123
15.2.7.3.2 Unified Anti-monopoly Enforcement after the Reform	1124
15.2.7.3.2 Private Implementation of China's Anti-monopoly Law and Establishment of the IP Court of the Supreme People's Court	1125
Chapter 16: Country Report – South Africa	1126
16.1. Introduction	1126
16.2. Part a: background.....	1126
16.3. Digital Economy Growth levels in the last 5 years	1133
16.4. What is the institutional framework for the digital economy?	1136
16.5. Institutional architecture.....	1139
16.6. PART B: COMPETITION REGULATION	1139
16.6.1. Cartels:	1140
16.6.2. Abuse of dominance	1141
16.6.3. Mergers	1142
16.7. Conclusion	1145
Annex I*: Private Governance of Digital Platforms: Case Studies	1151
1.1. Google/Alphabet*	1151
1.1.1. Nature of the competitive game.....	1151
1.1.1.1. Corporate Organisation Data	1151
1.1.1.2. Interlocking Directorates	1157
1.1.2. Corporate Growth Strategy: Business Models and Ecosystems.....	1158
1.1.2.1. Google.....	1159
1.1.2.1.1. Google Advertising	1160
1.1.2.1.2. Business Model and Ecosystem	1160
1.1.2.1.1. Structure of the Industry	1160
1.1.2.2. Android.....	1161
1.1.2.2.1. Structure of the Industry	1161
1.1.2.2.2. Business Model	1162
1.1.2.2.3. Ecosystem.....	1163
1.1.2.3. Google Shopping	1164
1.1.2.3.1. Structure of the Industry	1164
1.1.2.3.2. Business model.....	1165

1.1.2.3.3. Ecosystem	1165
1.1.3. Summary of the Case study	1166
1.1.3.1. Contractual Governance	1166
1.1.3.2. Soft or informal governance	1166
1.1.3.3. Conclusion	1166
1.2. Amazon*	1167
1.2.1. Nature of the competitive game	1167
1.1. Amazon's story of growth	1167
1.2. Corporate subsidiaries	1168
1.2.2. Business Models	1170
1.2.3. Ecosystem	1171
1.2.3.1. Amazon Marketplace	1171
1.2.3.2. Governance between Amazon and retailers	1172
1.2.4. Needs and barriers	1174
1.2.5. Summary of the Case study	1175
1.3. Airbnb*	1175
1.3.1. Nature of the competitive game	1175
1.3.1.1. Airbnb's story of growth	1175
1.3.1.2. From homesharing to hotel business: Airbnb's reconfiguration of markets	1176
1.3.2. Business Models	1177
1.3.3. Ecosystem	1178
1.3.3.1. Contractual Governance	1181
1.3.3.2. Soft Governance	1181
1.3.3.3. Technological Governance	1182
1.3.4. Needs and barriers	1182
1.3.5. Conclusion	1182
1.4. Tinder*	1183
1.4.1. Nature of the competitive game	1183
1.4.1.1. The specificity of the online dating industry	1183
1.4.1.2. The online dating value chain	1184
1.4.1.3. A rapidly-changing horizontal competition	1185
1.4.2. Tinder's Ecosystem	1186

1.4.2.1. 1 st layer: the other nine platforms owned by the Match Group.....	1187
1.4.2.2. 2 nd layer: direct competitors	1187
1.4.2.3. 3 rd layer: social networking platforms	1188
1.4.2.4. 4th layer: Users (P2C relations)	1188
1.4.2.3.1. Contractual relationship and potentially abusive clauses.....	1189
1.4.2.3.2. Soft and informal communication: image and communication	1190
1.4.2.3.3. Technological landmark and innovative reputation.....	1190
1.4.3. Business models.....	1191
1.4.4. Needs and barriers.....	1192
1.4.5. Conclusion	1193

1.3.1. Value of the consideration within the meaning of Sec. 35 1a no. 3 GWB and Sec. 9 (4) KartG.....	1291
1.3.1.1. Assets and monetary benefits included in the calculation	1291
1.3.1.2. Relevant date for the value assessment	1292
1.3.2. Substantial domestic operations	1293
1.3.2.1. Domestic Operations.....	1293
1.3.2.2. Significance	1294

I. Introduction

We are happy to present the Draft BRICS academic report on *Digital Era Competition Law: A BRICS Perspective*. The report engages with one of the most crucial questions of our time, the public governance of the digital economy, in particular focusing on the new forms of competitive interaction in the era of digital capitalism. New questions emerge out of the transition from the old to the new economy, which require ‘outside of the box thinking’ in order to inform policymakers and help to broaden the current narratives. Competition authorities have recently engaged in significant preparatory work, often in partnership with academics, in order to reflect on the challenges set by the digital economy to modern competition law enforcement. There have been a number of insightful reports already published the last few months and more work in the making. None of these reports has nevertheless so far engaged with the rapidly developing digital economy of emerging and developing jurisdictions, and in particular the BRICS, which represent a third of the world economy and a significant part of the global digital economy.

This gap was identified by the heads and representatives of the five BRICS competition authorities in the meeting of the BRICS Competition Authorities Working Group on Digital Markets at Sochi in September 2018, which, following up an exploratory report presented by Professors Ioannis Lianos and Alexey Ivanov, commissioned the BRICS Competition Law and Policy Centre established by the HSE-Skolkovo Institute for Law and Development, to prepare an academic report. This report would aim to explore the broader challenges the digital economy sets for competition law enforcement and to reflect on a new theoretical framework and some policy recommendations for the BRICS competition authorities to consider in their enforcement and policy work. The academic report would complement the BRICS Authorities’ Digital Markets Working Group report, which was prepared in parallel and which would present the vision and priorities of each of the BRICS competition authorities with regard to competition law enforcement in the digital economy.

In this work, the BRICS Competition Law and Policy Centre, under the leadership of its Director Professor Alexey Ivanov and the academic guidance of Professor Ioannis Lianos, established a network of academic collaborations with a number of BRICS partners and international partners in order to complete this task. In addition to the HSE University in Russia, the BRICS academic partners included Insper and FGV Sao Paulo in Brazil, JIRICO at O.P. Jindal Global University and CUTS International in India, Shanghai Jiao Tong University and Peking University in China, the University of Cape Town in South Africa. The work of these BRICS-located teams was coordinated and led by Professor Ioannis Lianos, the academic director of the BRICS Competition Law and Policy Centre, and was supported by the team of the Centre for Law, Economics and Society (CLES) at UCL Faculty of Laws in London, and a team of international academics, in particular Pro-

fessors Nick Economides, Hamid Ekbia, Bjorn Lundqvist, Evgenia Motchenkova, Pierre Regibeau, Nicolo Zingales and Dr. Hans Hendrik Eller, Mr. Andrew McLean, Dr. Igor Nikolic, Dr. Azza Raslan and Dr. Matthew Jay Strader.

The work of the BRICS academic team was inspired and supported by an international advisory board, headed by professors Eleanor Fox and Josef Stiglitz, with the participation of Professor Aditya Bhattacharjea, Dr. Cristina Caffarra, Judge Dennis Davis, Professor Nicholas Economides, Mr. Evgeny Kaspersky, Professor Lawrence Lessig, Professor Tshilidzi Marwala and Dr. Evgeny Morozov, who will play a significant role in the next phase of the consolidation of the final report to be released in November 2019.

We would like to express our profound gratitude to the heads and the staff of the BRICS competition authorities for their support during the preparation of this report. In particular, our thanks go to the head of the Russian FAS, Professor Igor Artemiev, and to the President of CADE in Brazil, Alexandre Barreto de Souza, who co-chair the digital markets group at BRICS, as well as the deputy head of FAS Professor Andrey Tsarikovskiy, for their gracious support during the preparation of this report and for enabling the coordination with the wonderful team preparing in parallel the BRICS authorities report led by Ms. Patricia Alessandra Morita Sakowski. The BRICS competition authorities offered invaluable support, by providing information whenever asked, completing a competition authorities' survey and helping the BRICS academic teams to organise a series of stakeholders' workshops in all BRICS jurisdictions.

The team took indeed an evidence-based approach to the preparation of the report. Our aim was to combine the insights of academia with information collected 'on the ground' in the course of a number of workshops held in each jurisdiction with the local stakeholders, including start-ups, large digital firms, legal and economic practitioners active in the digital economy, representatives of consumer associations and the local academic community. The workshops were co-organised with the international partner of the project, CLES@UCL and local partners. Following a preparatory meeting held in London in November 2019, five stakeholder workshops were held, first in March 2019 in Delhi (co-organised with CUTS International), then in April 2019 in Peking (co-organised with Peking University), followed by workshops in Moscow in June 2019 (co-organised with HSE), in Sao Paulo in July 2019 (co-organised with Insper) and in Pretoria in August 2019 (co-organised with the South African Competition Commission). In addition, the provisional results of the research were discussed in preparatory open conferences held in Moscow in December 2018 and in St. Petersburg in May 2019.

This intensive authorities-academia collaboration, at a transnational and global level, is quite unique and certainly contributes to the richness of the perspectives offered in this report. Our aim was to offer a critical discussion of the current debate, but also to contribute to the global discussion over the role of competition law in the digital age by offering a distinct development perspective that we consider is key for the BRICS countries and other emergent economies around the world, and which, in our view, was not the focus of all other projects undertaken on this issue in the more developed jurisdictions. We were particularly interested in putting at the centre of our study the process of value

extraction and capture in operation in the digital economy, and to draw lessons from these processes for the optimal design and enforcement of competition law.

This research would not have been accomplished without the contribution and support of a number of junior and senior academic colleagues, from the BRICS countries and beyond. We thank all the teams that have contributed during the last year to this difficult task under very tight deadlines. They had to deal with the relative paucity of information, as this is the first research effort undertaken on the BRICS enforcement activity in the digital economy and on the overall digital ecosystem in each of the BRICS countries. In addition to the members of the various BRICS teams, we would like to thank some anonymous reviewers of the country reports, and professors Aditya Bhattacharjea, Paulo Burnier da Silveira, Geeta Gouri, Marcio de Oliveira Junior.

Special thanks go also to Dr. Lyubov Koroteskaya, Dr. Irina Atrokhova and Mr Ryurik Kislov from the HSE University, and Lisa Penfold and Tatjana Wingender from UCL for their administrative support in the organisation of the preparatory and stakeholder workshops as well as to the team of dedicated editors that have worked under very tight deadlines.

Coming to the most important contributors to this work, the BRICS academic teams we would like to thank the following:

In **Brazil**, Professors Caio Mário da Silva Pereira Neto and Paulo Furquim de Azevedo, Mr. Bruno Polonio Renzetti, Dr. Murilo Otávio Lubambo de Melo, with the assistance of Helena Secaf and Felipe Bispo from FGV Sao Paulo and Insper.

In **Russia**, Dr. Maksim Karliuk, Igor Kharitonov, Daria Kotova, Olga Nizhegorodtseva, Ekaterina Perevoshchikova, Anna Pozdnyakova, Ekaterina Semenova, Dr. Elena Voinikanis, Thomas Blozovski from the HSE-Solkovo Institute for Law and Development and Professors Svetlana Avdasheva, Svetlana Golovanova, Natalia Pavlova and Ms Karina Ionkina, Mr. Alexey Konovtsev, Ms Dina Korneeva, Ms Olga Markova and Anton Morozov from the Economics Department at the HSE University.

In **India**, Ujjwal Kumar, Swasti Gupta and Poulomi Ghosh from CUTS International, Professor Shilpi Bhattacharya from Jindal Global Law School and Professors Avirup Bose, Indranath Gupta and Manveen Singh from JIRICO at Jindal Global Law School.

In **China**, Professors Xianlin Wang, Liyang Hou, and Xiang Fang, PhD students Fujing Zhan and Peicheng Wu from Shanghai Jiao Tong University, and Professor Jun Xue and Mr. Bowen Wang from Peking University, and Qiang Yu from the HSE-Solkovo Institute for Law and Development.

In **South Africa**, Judge Dennis Davis from the University of Cape Town and Ms. Tamara Paremoer from the Competition Commission of South Africa, with the support of Dr. Azza Raslan (World Bank).

In London and Paris (**CLES at UCL**), the team was composed by Andrew McLean, Dr. Klaas Hendrik Eller, Tobias Kleinschmitt, Miao Roujia, Pan Luyao, Heloisa Meirelles Bettiol, Paula Chueke Rabacov Zeina Alsharkas, and Dr. Amber Darr.

We hope that the report of the BRICS academic team will contribute to the global debate on the role of competition law in the digital economy and will provide the opportunity to the broader competition law and economic community as well as the general public to engage with the exciting developments and challenges that the digital age sets for competition law enforcement.

Professor Ioannis Lianos

Academic Director, BRICS Competition Law and Policy Centre, HSE University

Chair of Global Competition Law and Public Policy, & Director, Centre for Law, Economics and Society (CLES), Faculty of Laws, UCL

Professor Alexey Ivanov

Director of the BRICS Competition Law and Policy Centre and of the HSE-Skolkovo Institute for Law & Development, Associate Professor, Faculty of Laws, HSE University

II. Executive Summary

The Macro level: Digital competition – Technology and Business Environment (Chapter 1)

Digitalization has played a major role in globalization. However, at the same time, it accelerated the dramatic **growth of inequality** on the global and local scales, making this one of the key challenges for the further advancement of the digital economy. Developments in machine learning, advances in computing power, blockchain technology and data availability (including big data and smart data) will alter the global economy even further in the direction of digital capitalism. The emergence of the **fintech industry** provides an illustration of the complex interplay between the processes of datafication and financialisation and the emergence of specific forms of digital competition that may look different from the competitive process in the ‘Old Economy’. These developments come with many risks and problems of ensuring competition in the digital environment, especially in the face of the growing power of digital platforms, and rising inequality.

The current policy responses to these challenges posed by advances of the digital economy are often falling into ‘a mechanistic trap’, the mechanistic legal tradition established during the previous stages of the industrial development. This often leads to **fragmented and disconnected legal regimes** for each of the digital economy phenomena (i.e. big data, digital platforms, social networks and AI), without any effort to define an integral vision for a digital future that is desirable from a social contract perspective. This ‘mechanistic’ approach helps to retain the status-quo without establishing strong, transnational, countervailing regulatory regime(s) for the digital giants. This makes the creative development of the competition law toolkit and a **more holistic perspective on its interactions with other legal fields** even more crucial. As the competition law historically was meant to add flexibility to the regulatory environment and to address challenges of economic transformation caused by the technological development during the industrial revolutions of the past, it can be a useful again to deal with similar challenges set by the digital economy – growing inequality and economic unbalances.

The **BRICS countries** occupy a significant place in the global digital system, despite important differences within the group. BRICS countries, though sufficiently diverse, have much to gain from increasing digitalization in terms of overcoming internal challenges and enhancing their role in the global economy. The BRICS countries have integrated digitalization into their strategic policies and developed government strategic management tools to promote digitalization. They have followed a measured approach to regulating the digital sphere, while taking care not to stifle new and emerging markets and technologies with overregulation. BRICS cooperation aims to embrace the peculiarities

of globalization in its current phase. What is common for the BRICS jurisdictions is that they are all in search for a solution allowing to shortcut the developmental track. This experimentalist energy and creativity, which is a characteristic of the group, is extremely important during the current phase of global economic development. It is not only the institutional structure of the global order that is in transition but also the very nature of the global marketplace.

While hindering efficient expansion of digital players can prevent innovation and decrease consumer welfare in a dynamic setting, the global aspect of digital markets also entails issues of **distributive justice**. Competition policy could be guided by a more nuanced approach, recognizing the countries' relative positions along the **global value chains** and the possible distributive implications of competition law enforcement.

This includes approaches focused on '**digital sovereignty**', a definitive part of which is data sovereignty. The long-term trend in digital trade is erasing the boundaries between goods, services and intellectual property. Data is effectively becoming the new fuel of global economy. These changes raise profound regulatory challenges for global digital trade and cross-border data flows. Regulators must confront competing interests including those revolving around **data protection** and **economic development**.

Barriers that hinder cross-border data flows inevitably influence digital trade. **International economic governance** has achieved a great deal of institutionalization and some results in terms of enforcement. In any case, regulatory cooperation seems to be the way forward for the international governance of the digital economy, which may constitute points for convergence for future regulation. This requires a parallel agenda on building up the confidence of domestic regulators to allow data to leave the jurisdiction without undermining regulatory goals. The claim is that the model for the future will be based on persuasion and a global community of shared approaches with a structured engagement for coordination and harmonization. The approach by BRICS countries should respond to the dynamic needs of the digital economy and has the potential to shape a new common discourse in the area. One may distill from the above some general directions:

- The key focus of the new global competition policy should be the **facilitation of openness among global networks and value chains** through the reduction of the manipulative and exclusionary potential of digital platform and the elimination of barriers imposed on the global diffusion of innovation by both the global technological monopolies and cartel-like technological joint ventures burgeoning within their "walled gardens" at the expense of consumers, entrepreneurs, and the general public.
- A **human-centric approach** to the IP rights protection and the promotion of **open access and data commons regimes** can be included into the competition assessment matrix ensuring systemic resilience and sustainable development

- It is desirable to keep trying to **establish an effective global regime** for the protection of fair and equitable competition in the digital economy. Today such global legal framework does not exist. The BRICS countries have to play a key part to play in the development of a structured engagement for **international coordination**, based on a community of shared approaches and standards to deal with international cross-border data governance and its competition effects.
- Competition authorities need to analyse carefully the interactions within traditional banks, Fintech and Big Tech, and monitor market developments in order to **identify tipping points and potential bottlenecks** that might lead to emergence of dominant financial platforms and exclusion of competitors from the market.

The Economics of Platforms – theories of harm, efficiencies and methodologies (Chapter 2)

In the last decade, BRICS competition authorities have obtained records on competition enforcement towards Multi-Sided Platforms (hereinafter MSPs). Under enforcement of competition legislation, theories of harm in investigations and decisions are mostly of an exclusionary, not exploitative, nature. Exclusionary discrimination and tying are typical qualifications of anticompetitive conduct. Exclusionary effects are important competition concerns under merger approval.

MSPs organize interactions between users so to **internalize cross-side network externalities**. Learning about the business model of the platform (or platforms), a taxonomy of MSPs from the interaction of and the pricing to the sides of the platform becomes an important starting point. Supply side characteristics of MSP are relevant as well, with the presence of economies of scale and learning by doing, and innovation intensive business models.

The cross-side network effects are central when evaluating substitution patterns and price effects for each platforms and, more important, cross-side effects. These effects influence **market definition** under the Hypothetical Monopolist test and SSNIP tests. If cross-side effects are positive, a price increase on one side that is profitable under a one-sided analysis might become non-profitable. The decrease in sales on side A of the hypothetical monopolist's platform reduces sales on side B, which is typical of cross-side effects, that further provides feedback and reduces sales on side A further. Not taking into account the cross-platform effects would lead to define markets too narrowly.

The supply side characteristics of MSPs, which they share with other digital businesses are relevant for understanding platform related leveraging. These platforms often experience scale and learning economies. This interacts with innovation-based competition dimensions and large start-up or fixed costs.

Following the step of market definition, any **concentration measures** may not be informative of the market power of the platform. First, platforms are often innovation-based, disrupting businesses and market shares may change rapidly as in any market characterised by dynamic competition. Second, MSPs are differentiated products, where mark-ups are weakly associated with concentration measures. Third, pricing formulas in transaction or non-transaction platforms show that standard Lerner indices are invalid when calculated using costs (or prices) from one side of the platform. Lerner indices for MSPs must incorporate the cross-side effects.

Any **inference on anticompetitive price effects** from mergers may be obtained by expanding price pressure indices for two sided platforms. GUPPI/UPP like formulae highlight that cross-side effects amplify the increase in price pressure, say, on the price of side A of the merged platform 1, as an increase in demand on side A of merged platform 2, would boost sales in side B of platform 2. This second effect reinforces the incentives to increase prices in side A of platform 1. Only if the cross-side effects are not present, using the standard formula would not underestimate the effects.

As in any other market, **exclusionary practices** may also be observed in MSPs. The nature of MSPs requires four changes in the usual investigative tools and effects analysis. First, Price-cost comparisons in MSPs are not recommended, as optimal pricing formulas, with no exclusionary or abusive intent generate below cost pricing. Second, the network effects and issues of single- and multi-homing, generate 'tipping' points in the demand for a platform. This can both consolidate exclusionary practices and make them more effective. Third, platforms often create markets, therefore solving information problems in markets. This institutional role of the platform can generate efficiencies (creating a market) that are very hard to quantify and balance with respect to competition across platforms or a benchmark without the platform. Fourth, learning-by-doing technologies generate dynamic competition exclusionary opportunities, as younger firms have cost disadvantages that may not disappear over time or predatory pricing practices recoup period have lower costs. These business dimensions become central in the analysis of exclusionary practices.

No restriction on **multi-homing** is a universal remedy under both investigations of infringements and merger notifications. Special attention to vertical restraints with exclusionary effects reflects post-Chicago law and economics concerns about incentives to restrict competition. In this respect, the approach of BRICS contradicts neither the economic theory of competition in platform markets nor the practice of developed countries. An important gap in the decisions is the efficiency defence; competition authorities rarely undertake this type of analysis. It seems that neither do companies under enforcement try to develop this line of defence. Decisions on MSPs in BRICS rarely use a specific economic theory of platform competition (if any do so at all). They mostly rely on the standard theory of competition.

Competition policy analysis of MSPs should recognize the **dynamic nature of competition** in such businesses. MSPs are often innovations that may create monopolization, while at the same time such dominance can be quickly erased by new platforms and

business models. While new ways of doing business require new analytical tools, such innovation markets are not unknown to competition authorities. A look at the less used tools in the known toolbox would help meet the challenge of competition policy analysis of MSPs, complementing the adapted tools described here.

Last but not least, the economic theory of platforms does not exclude **exploitative theories of harm**. However, BRICS competition authorities do not apply them. In some BRICS countries, specific regulatory requirements are designed to support inter- and intra-platform competition. Their impact on rivalry and efficiency should be studied further.

The private governance of digital platforms: looking beyond the streetlight (Chapter 3)

The **operating logic of digital platforms** is embodied in their **private governance regime**. Such regimes have been treated as a somewhat natural outgrowth of a business plan for long, entailing that the competition law response should be forbearance. Yet, recent studies show the **strategic and design-based dimension** behind private governance regimes which appear as crucial for the generation and capture of value for digital platforms.

To understand the centrality of private governance, the ‘global value chain’ framework of analysis as developed by Gary Gereffi serves as illustration. Here, private governance plays **the double role of enabling and regulating global production**. It provides the instruments, legal and other, that animate the value chain and connect chain actors with each other in order to accomplish an integrated production process. Such governance regimes can encompass contracts but also business routines and practices, logistics, reporting documents and practices, as well as reputation and trust. Generally, private governance encompasses legal, social, and technological/algorithmic elements of governance.

Based on an **empirical view at the governance structure of major digital platforms** from various business sectors, it seems worthwhile to distinguish between **platform-to-business (P2B)** and **platform-to-consumer (P2C) relations** and to locate governance regimes on a scale between “participatory/collaborative” to more “captive/intrusive” governance. Central criteria for this attribution are (1.) entry and exit barriers of the ecosystem; (2.) the degree of formality and transparency of governance instruments and conditions, (3.) the degree of customizability of the governance model and the platform use; (4.) the price model; (5.) the functionality of dispute mechanisms.

While P2B relations face regulatory constraints essentially through competition law, P2C relations are put under additional scrutiny by consumer and privacy law. The contractual governance regimes of **P2B relations** are used to create loyalty to the platform and consolidate it as a privileged channel for marketization of the respective goods and services. In addition, they guarantee a broad discretion of governance and busi-

ness development for the platform through tailored dispute mechanisms and rules of unilateral adjustment and termination. Essential clauses concern data transferability, price-setting, and suspension of service/membership.

In **P2C relations**, private governance serves the purpose of community-building in order to consolidate consumer loyalty and extract value from repeated transactions and activities on and off the platform which generate a data set that platforms aim to merge. To do so, they generally implement far-reaching privacy rules, while being complaisant on other aspects of the consumer experience (with lenient cancellation rules, a right to withdraw from contracts, return purchased items etc). Essential clauses concern the legal qualification of the agreement, rules on privacy, and liability.

The following **policy recommendations** are put forward:

First, any regulatory intervention needs to be assessed against its effects on the private governance of platforms. Given that there is high homogeneity across platforms in the private governance regime, public intervention can increase the standards for this level-playing field and generally lead to a fairer allocation of the surplus value (in a P2B context) and better data protection (in a P2C context).

Second, a promising way forward is the establishment of model clauses as is currently under way in Europe. This approach is however limited to a formal, contractual level of governance that leaves informal, social and technological levels unaffected.

Third, competition law is well-placed, probably better than any other legal regime, to capture the nuanced interplay between legal, social and technological governance and power that is characteristic for private governance. Hence, its more expansive use may be justified on comparative institutional analysis grounds.

The Meso Level – The need for a new conceptual framework for the digital economy (Chapter 4)

As the global economy incurs a process of transformation by the ongoing ‘fourth industrial revolution’, competition law is traversing a ‘liminal’ moment, a period of transition during which the normal limits to thought, self-understanding and behaviour are relaxed, opening the way to novelty and imagination, construction and destruction. There is need for the discussion over the role of competition law in the digital era to be integrated to the broader debate over the **new processes of value generation and capture in the era of digital capitalism** and the complex economy to which it has given rise to. This complex digital economy is formed by a spider web of economic links, but also their underpinning societal relations, between different agents. However, competition law still lives in the simple world of neo-classical price theory (NPT) economics, which may not provide adequate tools in order to fully comprehend the various dimensions of the competition game. The emphasis put recently by competition authorities on **multi-sided markets** in order to analyse restrictions of competition in the data economy illustrates the agents’ changing roles and the complexity of their interactions, as the

same agents can be at the same time consumers and producers while their personal data raw material for the value generation process.

It becomes therefore essential to uncover the new value capture and value generation processes in operation in the digital economy, and draw lessons for the optimal design and enforcement of competition law, rather than take the established competition law framework as a given and try to stretch within it a quite complex reality that may not fit this Procrustean iron bed. These approaches should engage with the **complex economics** of digital capitalism, and in particular the role of futurity and financialisation, personalisation and cybernetics.

These new developments, first, call for a re-conceptualisation of the **goals of competition law** in the digital era, as competition law moves from the calm and predictable waters of 'consumer welfare', narrowly defined, to integrate considerations of income/wealth distribution, privacy and complex equality.

Second, it also requires a revision of the current understanding of the nature of the competitive game, which only focuses on horizontal rivalry in product and eventually technology markets. This is of course an important dimension of competition, but hardly the most significant one in the current process of value generation and capture in the digital economy. Firms do not only compete on the product market dimension, but in the today's financialised economy, probably the most important locus of competition is capital markets. The **process of financialisation** has important implications for the development of digital capitalism, an issue that the Report explores in detail for the first time in competition law and economics scholarship. Financial markets evaluate companies in view of expected returns in the not so near future, often linked to the emergence of bottlenecks or the perception that a firm holds important assets and resources (e.g. data, algorithms, specialised labour). The role of financial markets' evaluation in driving business strategies in the era of digital and financialised capitalism is linked to the 'subtle shift of mindset' in digital capitalism 'from profit (and isolating mechanisms) to wealth creation (and the potential for asset appreciation)' as value is created by investing in assets that will appreciate.

Third, this calls for a consideration not only of horizontal competition, but also **vertical competition**, the competition for a higher percentage of the surplus value brought by innovation, and competition from complementary technologies that may challenge the lead position in the value chain of the incumbents (**vertical innovation competition**). Fairness considerations, among other reasons, may also lead competition authorities to not only focus on **inter-platform/ecosystem competition** but to also promote **intra-platform/ecosystem competition**, as this may be a significant element of the competitive game.

To implement this broader focus of competition law, we need to develop adequate conceptual tools and methodologies. A recurrent problem is the narrow definition of market power in competition law, whose presence often triggers the competition law assessment, and which is also intrinsically linked to the step of market definition. This

currently ignores possible restrictions of vertical competition, personalisation and the **predictive role of digital platforms**, which may become source of harm for consumers, the competitive process, or the public at large.

It is important to engage with concepts of vertical power and the Report develops a **typology of vertical power**, combining in an overall conceptual framework the various concepts of non-structural power that have been used so far in competition law literature and some new ones (positional and architectural power). This conceptualisation offers an overall theoretical framework for vertical power that is necessary for sound competition law enforcement, and which has been lacking so far. The Report also explores specific **metrics for vertical power**, although this is still work in progress.

Another important tool that competition authorities may employ in order to map the complex competitive interactions (horizontal and vertical) in the digital economy is the **value chain approach**. Although competition authorities have already used this tool in sector/industry inquiries, they have not in competition law adjudication. A value chain approach enables competition authorities to better assess the bargaining asymmetries across the various segments of the value chain that may result either from the lack of competition on the markets affected or from the central position of some actors in the specific network and their positioning in the value chain. This tool may complete the market definition tool.

The effectiveness of competition law in the digital age may be curtailed by the cross-side network effects linked to positive feedback loops, increasing returns to scope and scale, the intense learning effects linked to AI, and the propensity of digital markets to tip. Hence, competition law on its own may not be sufficient to address the market failures in the digital economy. One therefore needs to take a **toolkit approach** that would combine different fields of law and regulation, competition law playing a primordial role in this new regulatory compass. This toolkit approach may rely on different combinations in each jurisdiction, on the basis of the institutional capabilities and the relative efficiency of the various regulatory alternatives, any choice being between imperfect, if perceived in isolation, institutional alternatives.

On the basis of the above, the Report makes the following recommendations:

Incorporate in the current competition law framework the **insights of complex economics**, either at the level of the conceptual framework and operational concepts used by competition law authorities (e.g. tipping points, leveraging points), or at the level of the tools and methods employed (e.g. agent-based modelling, value chains). The BRICS competition authorities should invest in the development of new tools making greater use of AI and computational economics in competition law enforcement.

Adopt a **multi-dimensional perspective on the competitive game**, which focuses not only on horizontal competition but also on **vertical competition**, and which engages with the way the process of **financialisation and futurity** may alter the traditional competition law assessment.

Make more use of **vertical power and vertical power metrics**, as additional filtering tools for competition law enforcement. The Report offers a unified theoretical framework for the various illustrations of vertical power that have been used so far and suggests some new ones (e.g. positional and architectural power, panopticon power), as well as some first ideas on metrics.

Make use of the **value chain methodology** in mapping competitive interactions (horizontal and vertical) in the digital economy.

Develop a **toolkit approach** that combines competition law enforcement with other tools of intervention, including regulation, creating property rights on data, establishing countervailing powers to tame digital platforms, and promoting a **polycentric** vision of **competition law**.

Expanding the scope of competition law intervention and remedies (Chapter 5)

The digital economy raises important challenges for the scope of competition law: personal, material and geographical.

In view of the dominant role of digital platforms in the world economy, and the ‘winner-take-most’ competition game, where ‘superstar firms’ command growing market shares and become highly profitable, the labour’s share is in significant decline. The forms of labour in the digital economy have also dramatically changed. However, despite the **weak position of labour vis-à-vis the digital platforms**, there are fewer possibilities of labour to organise and collectively bargain with digital platforms, as this may fall under the scope of competition law and do not benefit from the labour law exception routinely recognised to trade unions. This may raise difficulties in **view of the changing nature of labour relationships** in today’s ‘gig’ or ‘collaborative’ economy and the collapse of the traditional binary divide between employment and self-employment. Of particular interest is the development of alternative work arrangements which are facilitated by digital platforms, which create new digital marketplaces to supply labour for temporary use (‘labour value platforms’).

Digitalization has also made possible the emergence of other value-generating activities that may not fit well within the strict boundaries of the concept of ‘labour’. These varieties of human activity not only contribute different forms of value that go beyond traditional labour, they also involve different social roles and different forms of relation to modern technology. We will refer to the concept of ‘**use**’ as a separate concept from that of labour.

The development of platform work raises interesting questions as to the respective scope of labour law and competition law in engaging with, and regulating, these new emerging labour market dynamics. Promoting **collective bargaining of ‘labour’ or ‘users’** and designing competition law so as to address issues of labour market power may

provide a possible solution to the power of digital platforms by taking a **countervailing power approach**.

Blockchain may also curtail the ability of competition regulators to identify the entities that would be liable for competition law infringements and to adopt appropriate remedies and sanctions and the Report explores options for addressing this problem.

The material scope of merger control may also be revisited and some jurisdictions (e.g. Austria and Germany) have already engaged with the adoption of '**value of the deal**' **notification thresholds**. We view positively these developments.

The most important issue curtailing the ability of competition authorities of BRICS but also emergent economies to deal with the global digital giants that have emerged are issues of international comity and also **effectiveness of enforcement jurisdiction** (competition law remedies) This arises in particular if remedies are imposed on companies which do not have significant assets in the specific jurisdiction. A possible way out of this conundrum is to enhance **international cooperation**, also in designing appropriate remedies, in particular during today's globalized and digitalized economy.

The choice between competition law and other regulatory regimes is also an issue that needs to be explored by each jurisdiction according to its specific circumstances. The **creative interaction between competition law and other regulatory regimes** on data protection, interoperability, data portability, at the level of building specific theories of harm for the digital economy opens an important space for experimentation for competition authorities in the future.

Redesigning competition law enforcement for the digital age also requires the following two changes.

First, it becomes important to **ensure the rapidity of competition law enforcement** so as to avoid acting in situations when market tipping has already occurred and it might prove impossible to reverse the anticompetitive outcome, by adopting more easily interim measures, eventually commitment decisions and reforming the judicial review standards of competition authorities' decisions.

Second, it is crucial to develop remedial action that takes into account the broad effects of the anticompetitive conduct, which might better reflect the complexity of digital markets. **Competition law remedies in the complex digital economy** include the use of various forms of separation (including structural break-up), preventive structural adjudication, *ex ante* or *ex post* regulation of algorithms, data portability, the expansion of data commons, the facilitation of data clubs and interoperability, self-regulation and co-regulation through the adoption of codes of conduct, competition by design. The Report explores in detail these various remedial tools.

The last Section of this Chapter offers a statistical **overview of competition law enforcement** in BRICS jurisdictions.

We proceed to the following broad recommendations (for reasons of space specific recommendations addressing each type of remedy are not included in this Executive Summary):

- Develop new competition law concepts and metrics and reflect on the way **protection of labour** considerations may be integrated in the current competition law framework. BRICS competition authorities should establish a **working group** exploring the competition law implications of **labour market power** by digital platforms, the interaction of competition law and labour, as well as explore the implications of **blockchain technology** for competition law adjudication and enforcement.
- Establish mechanisms that would promote the remedial effectiveness of BRICS competition law authorities, in particular vis-à-vis the global digital giants. A possible first step will be the **sharing of information**, between like-minded authorities, or in the context of existing cooperation networks (e.g. BRICS) that could be organized by different MoUs, one dealing with merger issues and one with antitrust. Some prior informal communication and concertation may also be fruitful for developing BRICS-wide remedies that may address competition law problems that could be of concern for all or a number of BRICS jurisdictions. This cooperation could even take the form of **BRICS-wide or global commitments** by the digital platform to the authorities, the latter acting jointly. These processes may be combined with the sharing of analytical tools, industry intelligence and best practices in the context of a BRICS research consortium or common research platforms.
- Ensure the adoption of an efficient procedural framework and a more **targeted and intensive use of interim measures**.
- Develop a **holistic framework for competition law remedies** in the complex digital economy, by issuing **remedial guidelines**, at the BRICS level, that would state the law in each jurisdiction and could eventually attempt to frame some common broad remedial principles or meta-principles that should drive remedial action.

Ensuring efficient and fair distribution of products and content (Chapter 6)

Although platforms offer but one possible channel for sellers to bring products to the market, they provide a readily available distribution network and unprecedented scale at great convenience, which is virtually impossible to match for sellers. However, there is increasing tension between the attractiveness of this model and the **potential cannibalizing effects** that relying on platform sales might have on one's own distribution channel.

MFN clauses play a crucial role in that regard, as they enable platforms to ensure price parity with other channels. Hence, the stance that competition law takes in regard to

these practices can have significant effects on the structure of the retail market. An important related question is the extent to which **outright bans on distributors to use platforms or price comparison tools** are compatible with competition law. This is typically not an issue in BRICS jurisdictions, where platforms have been perceived as offering a unique opportunity to reach the target audience and enforce selective distribution systems, facilitated by the increased ability to monitor and detect deviations. However, for the same reasons digital technologies also facilitate the enforcement of **RPM and price discrimination**, for instance through geoblocking, geofiltering and other technological protection measures.

With regard to **content distribution**, it was noted that there are reasons to doubt that BRICS jurisdictions will condone the extension outside the EU of the contractual restrictions imposed by copyright owners in reflection of the stricter copyright regime. This suggests that BRICS economies are likely to maintain a different landscape in distribution and copyright enforcement, despite the global or macro-regional nature of prevalent platform businesses.

With the increasing platformization of retail, perhaps the most contentious topic is the compatibility with competition law of the **dual role played by e-commerce operators**, which serve both as “referees” in the marketplace and as “players” in the retail market. This is currently being investigated or has been subject to investigation in several EU jurisdictions, the US, Russia and India. India has gone as far as issuing a comprehensive regulation on foreign direct investment policy that forces foreign-owned platform to be merely a marketplace, rather than provide products through their own inventory. Such platforms are also prohibited from imposing exclusivity and directly or indirectly influencing the sale price of goods or services. Whether this *ex ante* approach is preferable to antitrust enforcement and is likely to be followed by other BRICS jurisdictions remains to be seen.

What is clear is that in this new technological environment competition authorities and courts are called to play increasing attention to the dynamics of competition within and across platforms ecosystems. In doing that, authorities should be cautious with the application of the so-called **agency immunity**, as that applies only under restrictive conditions. Most notably, the immunity cannot apply where one of the parties has significant market power, either in the intermediation market or in the market for the product or service that is being sold. Furthermore, there is reason to read the evolution of the agency doctrine to suggest a carve-out in situations of dependence deriving from superior bargaining power. Finally, the immunity cannot be invoked where the arrangement between the putative agent and principal involve horizontal collusion. This is an area that has seen significant enforcement, particularly in Russia and India, where authorities have condemned platform-enabled hub and spoke agreements. Once again, we can wonder whether it would be optimal to extend this approach across BRICS.

Exclusionary and unfair unilateral practices in reference to the digital economy: updating the current framework (Chapter 7)

There is an intense academic discussion regarding whether consumers and business users are exposed to conduct that may amount to competition law abuses when using services on the Internet. The discussion is connected to the Internet phenomenon of 'platforms' or intermediaries, i.e. Internet sites where users and potential purchasers of services and products are matched and interact with advertisers, business users, service provider or suppliers.

There is a relevant discussion regarding the restraints the **system leaders of the platforms or ecosystems** burden the business users connected to the ecosystems. Indeed, intra platform or intra ecosystem competition is a relevant notion. Successful platforms that have been able to tip the market for the platform service may obtain power not only in reference to the platform service market, but more importantly also in reference to the connected business users utilizing the service. Indeed, the system leader controlling the platform has gained power in the whole connected ecosystem to the point where it commands the interaction of the ecosystem.

In reference to data, several Internet sites, devices and machines are already today equipped with sensors to collect data and devices may run software to control and make interoperable the functioning of machines, but also to enable the interoperable smart kitchens, vehicles, and even cities. The system leaders of these smart interoperable systems may act as **gatekeepers**, controlling and locking-in customers, while excluding or limiting interoperability with other systems, specific device or machine-producing firms and customers, based on the access, use and re-use of data.

The chapter analyse exclusionary and unfair unilateral practices in reference to platform. May preventing **interoperability**, access to ecosystems or IT-systems and preventing **portability of data**, be considered abuse or monopolisation? Should **discrimination**, by not creating a levelled playing field, or by not displaying similar business users, on equal term, in search results or on product/services comparison sites be an abuse? Can **restricting access to data** be an abuse?

With regard to abuse, several jurisdictions focus on **leveraging**, while also identifying that the contracts between firms in the ecosystems may very well include **exclusivity on semi-exclusivity** clauses. The alleged abuses seem to be centred around platforms. Platforms may be used to favour or discriminate to the benefit of affiliated or directly owned firms in downstream, neighbouring or upstream markets. Indeed, platforms that have gained leading positions in the ecosystem have the power to exclude competitors or to lock-in customers or business users. In addition, their control and use of data regarding their customer and users, and their financial resources contribute to their leading roles within their respective networks vis-à-vis business users.

A way to resolve the issue of whether using network effect and tipping to gain monopoly would amount to an abuse, is to utilize the **principle of special responsibility**. When

a platform driven by indirect effect has been established, the system leader controlling the platform is allowed to continue operating the platform, yet he should be considered as the regulator of the connected ecosystem or network. There will be little, if no, competition for that network or ecosystem and the system leader therefore has a special responsibility to preserve competition by creating a levelled playing field for downstream and connected markets, similar to the duty of a regulator to ensure that the regulated market produces outcomes equivalent to those of a competitive market.

Dealing with algorithmic collusion (Chapter 8)

There is now significant literature (although less empirical research) indicating that the use of algorithms not only facilitates explicit agreements between firms, it can also result in tacit coordination and, moreover, **facilitate tacit collusion**. Analysis of the existing models of algorithmic collusion implies that it is possible for independent algorithms to coordinate and sustain prices close to collusive level.

Both the use of algorithms to monitor and enforce existing agreements and coordination by pricing algorithms themselves not only facilitates tacit and explicit collusion but also makes it more difficult to detect the violations. **Detection** would become more difficult as there would be fewer opportunities to obtain hard evidence. At the same time, the range of detection tools will have to be expanded including **new software screening tools** and **new regulatory agencies with experience in IT and AI**. These agencies should have a capacity and expertise to be able to detect, document and verify the use of prohibited algorithms or algorithms that can be potentially harmful for consumer welfare. **Per se prohibition of certain types of algorithms** can also be an option. Also other policy instruments, such as e.g. leniency programs, will have to be redesigned.

From the legal perspective, we conclude that the current **antitrust concept of collusion** and its emphasis on communication is not sufficient to take into account all forms of algorithmic collusion. It is probably sufficient for the situations of coordination on pricing algorithms and third-party-pricing. But it is not sufficient for the situation of autonomous tacit collusion by **learning algorithms** themselves.

The policy options for competition law and competition policy to deal with the increasing threat of algorithmic collusion at the moment seem to be rather limited. Algorithmic collusion could be considered as a violation of competition law only if the **concept of an agreement is extended** to cover also this new type of collusive behaviour. But even then, serious difficulties remain with respect to the detection as well as the verification of algorithmic collusion. The Report explores the following options:

- As a first step, competition authorities should support (and engage in) **empirical work** on algorithmic collusion. They should also revisit their application of the existing legal framework in situations of algorithmic collusion, eventually by considering that certain types of algorithms may constitute '**super plus**' **factors** facilitating collusion. They should also develop algorithmic tools to detect

collusive activity, following the example of some BRICS competition authorities, in particular in Brazil and in Russia.

- As a second step, competition authorities should revisit their understanding of collusion as engaging some form of communication, and legislators should reflect on the cost and benefits of **expanding the concept of antitrust collusion** to cover situations of collusion by learning algorithms.

Reforming merger policy (Chapter 9)

From Facebook acquiring WhatsApp and Instagram to Microsoft buying out LinkedIn, Skype and Github or Google swallowing Motorola Mobility, DoubleClick or Nest Labs, mergers and acquisitions in the digital economy have been controversial. Some of the concerns have been fairly traditional.

While the development of the digital economy does not either call for a revolution in how we conduct merger control, it is likely to require some significant changes in competition guidelines and will require close coordination between competition authorities and other regulatory agencies.

The main characteristics of digital technologies are algorithms, data, bridging of distance and speed. These characteristics have a number of important consequences. **Algorithms** are difficult to fully grasp and even harder to police. This makes the detection of abusive conduct and the implementation of effective remedies harder. Stepping back, then, this might justify a tougher line for mergers which are likely to facilitate such abusive conducts. On the other hand, in our view at least, the purported effect of algorithms on companies' ability to implicitly collude does not have strong implications for merger policy, except maybe for having a closer look at mergers in somewhat less concentrated markets: if collusion is easier then the level of concentration at which it becomes feasible is also lower.

The bridging of distances has obvious implications for **market definition** when the merging parties take orders *and* deliver products online. A more subtle analysis is required when parties take orders online but still deliver goods or services physically. The relevant notion of "speed" is not speed of innovation. While many digital sectors are currently characterised by fast-paced innovation, there is nothing intrinsically "digital" to this trend. By contrast, it is because digital technology is fast (and spans distances) that network effects can arise much faster than in other sectors. This underlines the need for forward looking merger review and the possibility of using access/interoperability remedies.

The combination of algorithms and data has allowed unprecedented **targeting** of advertising to online consumers as well as a tailoring of the offers (including prices) received by each individual. This poses a serious challenge to our usual economic analysis of horizontal effects as well as to our traditional approach to market definition. In a very real sense, every individual becomes a "relevant" market, challenging traditional SSNIP tests and "market share-based" approaches to market power. Moreover, in such

an environment, the effects of a merger depend not only on the overlap between the customers served by each party but also on the amount and type of information that each party has about those customers. Unfortunately, economic analysis of competition in such settings, while already useful, is not yet mature.

Finally, while the role of data in digital competition is undeniable, we currently lack the information required to derive **broad principles** as to how data should be considered in merger review. The main problem is that, for a merger, it is mostly the *marginal* return to data which matters: would the combination of the data held by the two parties significantly raise barriers to entry? Would it generate significant merger-specific efficiencies? There is simply no publicly available information to allow us to at least establish some presumptions in the matter.

Notwithstanding these difficulties, the Report includes the following recommendations:

- Competition authorities should focus more on data and the way mergers may affect competitive rivalry in particular in view of **horizontal overlaps** between the merging parties when data is the relevant product.
- Regarding **data as inputs** in the production process, competition authorities should pay more attention to factors or deliberate strategies, which might hamper **access to resources** (such as data, or skilled labour). For example, contractual clauses or “gentlemen’s agreements” preventing poaching or draconian non-compete clauses can restrict the flow of necessary skills, especially when the relevant labour markets have a significant local dimension (e.g. Silicon Valley).
- Competition authorities should focus on **‘attention markets’** as digital platforms operate as “attention brokers”, whose main goal is to attract users and get them to spend time in their respective “ecology”. Hence, a platform’s ‘market power’ now depends on its ability to retain users within its own ecology and to use this to restrict the supply of advertising, leading to higher prices for both advertising and the corresponding products.
- Competition authorities should revisit the way they examine **counterfactuals** in merger control. In the context of the fast moving, from a technology and consumer preferences, perspectives digital economy, counterfactuals should inevitably become more speculative.
- Competition authorities should adapt the **standard of proof** for anticompetitive effects of mergers in the digital economy, in particular in markets with tipping effects, and should also re-think the **intensity of judicial review** of their decisions, in order to enable a more dynamic assessment of mergers and the use of more speculative theories of harm, such as restrictions to potential competition or harm to innovation.

Challenges ahead – Competition law at the era of the Internet of Things (IoT) (Chapter 10)

The chapter looked into the future developments with the advancement of 5G standard and the Internet of Things (IoT). We are increasingly seeing various objects connected to the internet and witness the gradual emergence of connected cars, connected domestic appliances, smart health devices and even smart cities. The successful implementation of IoT will generate many challenges, of which we identify the use and application of two different layers of standards – **‘infrastructure’ standards** that read on physical objects that enable connectivity between them (such as 5G and Wi-Fi standards), and **‘upper layer’ standards** that concern data acquired by IoT objects. In order for an IoT ecosystem to work efficiently we would need to have seamless connectivity between different IoT objects, and thus ubiquitous access and use of infrastructure standards, as well as access to data generated by different objects. For example, self-driving cars would all need to use 5G and other infrastructure standards and would need to share driving data between them.

The successful implementation of infrastructure and upper layer standards can pose different challenges. Namely, patents that read on infrastructure standards would need to be widely available and licensed. **Standard essential patents (SEPs)** are generally required to be licensed on fair, reasonable and non-discriminatory (**FRAND**) terms, but what exactly those terms mean is subject to diverging interpretations. Disputes concerning the licensing of SEPs are no longer only a US or an EU phenomenon, large high technology companies are increasingly using BRICS countries as a venue for litigation. However, the amount of litigation in BRICS countries is uneven and there is a lack of predictable rules and practices.

Data-sharing in upper layer standards presents further challenges. There is a tension between, on the one hand, the need to enable seamless functioning of IoT systems via data-sharing and, on the other hand, the need ensure privacy of individuals and compliance with data protection rules. In the absence of specific legal rules, competition law may potentially apply, or companies may voluntarily exchange data in **data pools** or use **blockchain** technologies. Combination of various measures could be used for enabling successful data sharing mechanisms.

The chapter offers the following policy recommendations:

- **Consider publishing ‘best-practices guidelines’ on FRAND SEP licensing practices and litigation** at a national and/or BRICS level. The aim of such guidelines should be to bring transparency and legal certainty to market participants. Guidelines should take into account current best practices from the EU and the US and must equally take into account the interests of both technology developers and standard implementers.
- **Consider adopting targeted sector specific legislation and promote the formation of data sharing platforms.** Such sector specific legislation should

identify critical areas where regulatory intervention is needed, while ensuring the compliance with data-protection rules. Regulatory authorities might also consider promoting the formation of data pools, but also ensure they do not cause anti-competitive effects.

Dealing with restrictions on privacy as a competition law problem (Chapter 11)

The recent controversy on the intersection of competition law with the protection of privacy, following the emergence of big data and social media is a major challenge for competition authorities worldwide. Recent technological progress in data analytics may greatly facilitate the prediction of personality traits and attributes from even a few digital records of human behaviour.

There are **different perspectives globally as to the level of personal data protection** and the role competition law may play in this context, hence the discussion of integrating such concerns in competition law enforcement at the BRICS level may be premature. However, a **market failure approach** may provide common intellectual foundations for the assessment of harms associated to the exploitation of personal data, even when the specific legal system does not formally recognize a fundamental right to privacy.

The Report presents a model of market failure based on a **requirement provision in the acquisition of personal information from users of other products/services**. We establish the economic harm from the market failure and the requirement using the traditional competition law toolbox. Eliminating the requirement and the market failure by creating a functioning market for the sale of personal information is imperative.

Besides the traditional analysis of the requirement and market failure, we note that there are typically **informational asymmetries** between the data controller and the data subject. The latter may not be aware that his data was harvested, in the first place, or that the data will be processed by the data controller for a different purpose, or shared and sold to third parties. The exploitation of personal data may also result from economic coercion, on the basis of **resource-dependence or lock-in of the user**, the latter having no other choice, in order to enjoy the consumption of a specific service provided by the data controller or its ecosystem, than to consent to the harvesting and use of his data. A behavioural approach would also emphasise the possible internalities (**demand-side market failures**) coming out of the bounded rationality, or the fact that people do not internalise all consequences of their actions and face limits in their cognitive capacities.

The Report also addresses the way competition law could engage with exploitative and exclusionary conduct leading to privacy harm, both for *ex ante* and *ex post* enforcement.

With regard to *ex ante* enforcement, it explores how **privacy concerns may be integrated in merger control** as part of the definition of product quality.

With regard to *ex post* enforcement, the Report explores **different theories of harm** that may give rise to competition law concerns and suggest specific tests for their assessment. In particular, we analyse **old and new exploitative theories of harm** relating to excessive data extraction, personalised pricing, unfair commercial practices and trading conditions, exploitative requirement contracts, behavioural manipulation.

We are in favour of collective action to restore the conditions of a well-functioning data market and the report makes the following recommendations:

- Reflect on **broader guiding principles on privacy-related competition law theories of harm** (from a market failure perspective). This could be done by a specific BRICS working group constituted to this effect.
- Explore legislative intervention **changing the 'default' regime for data harvesting from 'opt-in' to 'opt-out'** if the specific jurisdiction disposes of a data protection regime. This opens the possibility for a **possible compensation to the user for 'opting-in'** that is, for 'selling' his data. This may facilitate the **emergence of a licensing market for user data** for users opting-in to share their data with the platforms, thus dealing with the 'missing markets' problem and its associated effects.
- Facilitate the users to **collectively bargain** with the platforms rates for the payment they will receive for the data harvested in order to protect their personal data, thus neutralising the asymmetrical bargaining power of large digital platforms and digital giants.
- Promote **technological solutions** to the problem of restrictions to privacy by the business conduct of digital platforms or more generally user-initiated and driven practices that may frustrate the aims of the adds-based business models.

Chapter 1: The Macro level: Digital competition – Technology and Business Environment

1.1. Introduction

1.1.1. The Main Challenge of Our Digital Future

Shortly before his passing, astrophysicist Stephen Hawking, when answering questions from science fans on his page in the r/science community on Reddit.com, gave the following comment on our society's development prospects related to the on-going technological changes: "If machines produce everything we need, the outcome will depend on how things are distributed. Everyone can enjoy a life of luxurious leisure if the machine-produced wealth is shared, or most people can end up miserably poor if the machine-owners successfully lobby against wealth redistribution. So far, the trend seems to be toward the second option, with technology driving ever-increasing inequality".¹

This fear expressed by Dr. Hawking is not unfamiliar to the BRICS leaders. Russian President Vladimir Putin shared similar concerns while addressing an international audience at the St. Petersburg Economic Forum held on 6-8 June, 2019: "Monopoly always means concentration of incomes in the hands of the few at the expense of all the rest, and in this sense, attempts to monopolise the new technological wave, limiting access to its results, are taking the problem of global inequality both among countries and regions and within countries themselves to an absolutely new and different level. And we are well aware that this is the main source of instability. It is not only about the level of incomes, income inequality, it is about the fundamental difference in people's opportunities. In fact, in the making there is an attempt to form two worlds, and the gap between them keeps growing. Where some people have access to the most advanced systems of education, health, modern technologies, others have neither prospects, nor chances to

escape poverty, and still others are hardly balancing on the verge of survival”².

Chinese President Xi Jinping in his recent keynote speech at the World Economic Forum was also highlighting this problem emphasizing that “[t]he richest one percent of the world’s population own more wealth than the remaining 99 percent” and “[i]nequality in income distribution and uneven development space are worrying”³. And he concludes that growing global inequality “is the biggest challenge facing the world today”⁴.

The first-ever Digital Economy Report released on 4 September 2019 by the United Nations also highlights this problem, as noted by the UN Secretary-General António Guterres, in a foreword to the report: “Digital advances have generated enormous wealth in record time, but that wealth has been concentrated around a small number of individuals, companies and countries. Under current policies and regulations, this trajectory is likely to continue, further contributing to rising inequality”⁵.

Recent empirical research has revealed that over the last 25 years, the top 1% have gained more income than the bottom 50% put together and “[f]ar from trickling down, income and wealth are being sucked upwards at an alarming rate”⁶. As an outcome, since 2015, the richest 1% has owned more wealth than the rest of the planet⁷.

Risks of ignoring this problem may be extremely high. For example, Joseph E. Stiglitz points out in his well-known book “The Price of Inequality” that growing inequality leads to significant losses for societies and governments, as well as provoking development imbalances that result in long-term instability.

This is not just a problem of some individuals or even countries that had a run of bad luck and find themselves at the bottom of social or global hierarchy, but relates to a wider problem of performance, resilience and in the long run survival of the entire human society: “Widely unequal societies do not function efficiently, and their economies are neither stable nor sustainable in the long term”⁸, Stiglitz concludes.

Unfortunately, as this concern over a surge in inequality at the current stage of industrial revolution has actually become almost a truism in the current discussions about the digital economy⁹, very few actual measures to tackle this problem are implemented. The UNCTAD, which highlighted this problem in the recent UN Digital Economy Report, has

already been vocal about this for a number of years, as, for instance, in its 2017 annual report, it mentioned that “hyperglobalization has led to a considerable concentration of economic power and wealth in the hands of a remarkably small number of people”¹⁰.

Far from being solved, this problem is only getting worse against the backdrop of current technological shifts and the global economy’s transition to a new quality – the digital economy. Digitalization has played a major role in making the global economy more globalized and interconnected. But it has also probably contributed to another major redistribution of wealth on the global scale. There are different opinions on the factors that contributed to this redistribution of wealth happening in the context of the digitalization of the global economy. But it would be myopic not to pay attention to one particular phenomenon that is also closely related to the competition law and policy debate in the digital economy.

The growing world power of digital platforms, which like spiders drag an increasing number of economic activities and economic values into their digital webs, worsens rather than reduces the inequality problem. As the UN Digital Economy Report shows, the platform-based economy is growing fast with an estimated combined market value of the leading digital platform companies becoming 67 per cent higher just in a period of two years between 2015 and 2017, when it increased from 4 to 7 trillion USD¹¹. Add to this that already in 2018 and 2019 Apple, Amazon and Microsoft – three out of seven “super platforms” (Microsoft, Apple, Amazon, Google, Facebook, Tencent and Alibaba), each exceeded a \$1 trillion market valuation. At the same time, some empirical studies conducted recently show that the rapid process of digitalization during the past decade does not seem to have translated into strong productivity growth; on the contrary, that growth has slowed¹². According to the UNCTAD, global employment in the information and communication technology sector increased from 34 million in 2010 to 39 million in 2015, and the share of this sector in total employment rose over the same period, from 1.8 per cent to 2 per cent.

This quite limited achievement of the digital economy in bringing a rise both in productivity and employment on the global scale compared with the soaring market valuation of the major digital platforms could be a sign of a serious flaw in the legal and economic regulation of the digital economy in need of being addressed. The hyperglobalization and digitalization have become mutually supportive forces driving the growth of inequality in the global economy. Vladimir Lenin shortly after the Russian Revolution marking the destruction of the old world of empires and the beginning of painful transition towards a new economic order famously stated that “Communism is Soviet power plus the electrification of the whole country”.¹³ The modern leaders of digital capitalism

could say that the digital economy is market power plus the digitalization of the whole world.

This story of interlinked digitalization and globalization are important elements of a new mythology of the extractive or 'predatory' capitalism as Mariana Mazzucato¹⁴ has neatly put it. In her book on 'making and taking' in the global economy, she emphasizes the importance of storytelling and naming for defining actual economic policy. She notices that "[t]he confused and misleading approach to the concept of value that is currently dominating economics" is generating some paradoxical government policies – for instance, incentivizing unproductive activities like advertising that constitutes the main source of profits for the Internet platforms but not the activities that is of most importance for societies and cohesive economic development.¹⁵ One of the key consequences of this confused and misleading approach to understanding value creation and allocation, according to Mazzucato, is a government's failure to address an apparent connection between the digital monopolies and falling incomes of the global population. She highlights this connection through privatization of data in the sole interest of the corporate giants' profit maximization, that in its turn produces "a new form of inequality – the skewed access to the profits generated from big data".¹⁶

The concepts are important, and we have to keep in mind that with the advance of the digital economy and a number of new phenomena accompanying its development there would be more and more attempts to reframe the discourse in economics and law in the interest of the main beneficiaries of the new economic order. The UN Digital Economy Report emphasizes that "lobbying in domestic and international policy-making circles" is an important mechanism for global digital platforms to consolidate their competitive positions.¹⁷ Some narratives that are fed to the regulators all around the world can actually be intentionally confusing and hide the real meaning of things. Like a famous motto "Competition is just one click away"¹⁸ produced and promoted by Google in defense of abusive conduct accusations. Indeed, "a Google search for "one click away" produces over 9.5 million results, almost as many as "In God we Trust," slightly more than "girls just wanna have fun," and more than 50 times more than "God Save America", – calculated Eric Clemons, Professor of Operations Information and Decisions at Wharton Business School.¹⁹

"If names be not correct, language is not in accordance with the truth of things. If language be not in accordance with the truth of things, affairs cannot be carried on to success. When affairs cannot be carried on to success, proprieties and music will not flourish. When proprieties and music do not flourish, punishments will not be properly

awarded. When punishments are not properly awarded, the people do not know how to move hand or foot»,²⁰ – Confucius warns us in his Analects.

As not much has yet been done to help to change the current trajectory of the digital economy development leading to an ever-increasing market power of the digital platforms and soaring inequality, it is probably time to ask ourselves the question Confucius asked his students – if we indeed speak “in accordance with the truth of things”.

1.1.2. A Mechanistic Trap of Modern Competition Law

What is the actual meaning of the digital economy as a social phenomenon? Is this a new quality of the economic system? A real technological breakthrough? Or rather a new way to sell the old neoliberal vision of the global economy to the general public and policy makers to loosen regulation and allow monopolies to avoid proper checks and balances on their market power, just another marketing trick?

Evgeny Morozov sees the pervasive enthusiasm about the digital economy among the global business and expert leaders as another attempt to “make the idea of capitalism more morally acceptable”.²¹ He records how “capitalist thinkers still look to Silicon Valley and its culture with a glimmer of hope” as the digital economy “occupies a prominent role on the horizon of the Western capitalist imaginary” and offers “a promising field for regenerative mythologies”.²²

This ‘capitalist imaginary’ could be not a harmless thing. For instance, Mariana Mazzucato mentions that “in the absence of strong, transnational, countervailing regulatory forces, firms that first establish market control in the digital economy reap extraordinary rewards”.²³ Why would these “strong, transnational, countervailing regulatory forces” be still missing after so many years of debate about the growing inequality and disbalances in the world economy?

The UN Digital Economy Report reminds us that “technology is not deterministic” – it is totally up to governments and other stakeholders to “shape the digital economy” by defining the rules of the game.²⁴ So, it becomes imperative for governments all around the world to define these rules according to the nature of things belonging to the digital era. Ideally, if these rules could form a holistic vision for tomorrow’s society beneficial for all.

Ronald Dworkin has suggested that the legal system constitutes what is designed “to share the sense of purpose of the [legal] enterprise”, which is realized in society by all its members as inherently equal.²⁵ Without this framework of solidarity and common

sense of purpose, law as the mechanism for governing social development loses all its meaning.

Michael Agarkov, a prominent Russian and Soviet legal scholar, who lived through the major socio-economic transition of the early 20th century, noted that at the start of the 20th century “an integral world outlook had already ceased to exist, and science had to turn to the key issues of civil law, verify old truths, get rid of the obsolete and formulate anew its own basic premises”.²⁶ This search for “integral world outlook” is also clear to the present-day policy makers irrespective of the country where they work when they deal with the new phenomena of the digital economy.

At the same time, many regulatory attempts that we can see in the sphere of the digital economy are quite often fit into the mechanistic tradition in understanding law, a relatively simple model based on classification and linear logic. Legislators across the world are overwhelmed with heated debates over big data, digital platforms, social networks and AI – but are developing fragmented regulatory regimes for each of these phenomena without defining an integral vision of a digital future that is desirable. As a matter of fact, such a legislative work based on the mechanistic legal tradition often leads to a single practical outcome – it helps to retain the status-quo without a real search for answers to the “accursed questions” ranging from distribution of benefits and risks to the sustainable development of the digital economy.

Mechanistic law, through its conversion into a closed system based on certain classifications and linear logic, became a historical fact of the industrial era. Ugo Mattei and Fritjof Capra thoroughly examined this development of the law in the context of industrialization of the past century. According to them, the current outcome of the evolution of law has become its adjustment to the laws of industrial economics: “The mechanistic trap promotes a vision of the legal system as an aggregate of pre-existing legal rules that abstractly bind everybody, both the weak and the strong. This ideology makes plain, law-abiding people think of law almost as if it were a set of instructions to assemble a potentially dangerous appliance”.²⁷ The problem mechanistic application of law, to which the authors of the study refer as “a mechanistic trap” is that it constitutes, in their opinion, one of the gravest problems inherited by modern jurisprudence and legal practice from the industrial era.

Enthusiasm for machines and mechanisms at the time of the 20th century’s industrialization brought about a relevant mindset, which in many ways stripped law of the living spirit and by so doing made law unfitted to effectively meet the key challenge of today – a new stage of industrial revolution. The lower adaptability of law due to its mechanization and transformation into a closed system makes it poorly geared to the present-day challenges of the digital era. The key element of the new economic and social reality – an unprecedentedly high speed and multidirectional nature of the on-going change – was

well captured by the sociologist Zygmunt Bauman in his book “Fluid Modernity”.

Bauman has described the state of humanity at its current development stage through the properties of liquid:

“Liquids, unlike solids, cannot easily hold their shape. Fluids, so to speak, neither fix space nor bind time. While solids have clear spatial dimensions but neutralize the impact, and thus downgrade the significance, of time (effectively resist its flow or render it irrelevant), fluids do not keep to any shape for long and are constantly ready (and prone) to change it; and so for them it is the flow of time that counts, more than the space they happen to occupy: that space, after all, they fill but ‘for a moment’. In a sense, solids cancel time; for liquids, on the contrary, it is mostly time that matters. When describing solids, one may ignore time altogether; in describing fluids, to leave time out of account would be a grievous mistake. Descriptions of fluids are all snapshots, and they need a date at the bottom of the picture. Fluids travel easily. They ‘flow’, ‘spill’, ‘run out’, ‘splash’, ‘pour over’, ‘leak’, ‘flood’, ‘spray’, ‘drip’, ‘seep’, ‘ooze’; unlike solids, they are not easily stopped – they pass around some obstacles, dissolve some others and bore or soak their way through others still. From the meeting with solids they emerge unscathed, while the solids they have met, if they stay solid, are changed – get moist or drenched. The extraordinary mobility of fluids is what associates them with the idea of ‘lightness’ There are liquids which, cubic inch for cubic inch, are heavier than many solids, but we are inclined nonetheless to visualize them all as lighter, less ‘weighty’ than everything solid. We associate ‘lightness’ or ‘weightlessness’ with mobility and inconstancy: we know from practice that the lighter we travel the easier and faster we move. These are reasons to consider ‘fluidity’ or ‘liquidity’ as fitting metaphors when we wish to grasp the nature of the present, in many ways novel, phase in the history of modernity.”²⁸

What happens when the fluid digital economy encounters the mechanistic laws embedded in a solid form? It just bypasses such objects without any significant impact of the latter thereon. Or should the obstacle be large, such a solid object may block the movement of liquid, but as with any dam it is able to do it only to a certain extent.

It seems extremely important to recognize the fundamental nature of such conflict between our current laws and the liquid economic environment. It is not accidental that over a century ago when criticizing the scholastic realism of legal concepts, German philosopher Oswald Spengler stressed: “The future calls for restructuring of the entire legal thinking on the analogy with advanced physics and advanced maths”.²⁹

Today, humanity is faced with quite existential challenges: the current inequality level multiplied by the on-going changes related to the new industrial revolution bringing up similar questions. Far from being prepared for such challenges, we approach them armed with such means that hinder rather than help to overcome them.

29 Шпенглер О. Закат Европы. Т. 2. М., 1998. С.85-86. (O. Shpengler. The Decline of the West. V.2,M., pages 85-86)

In a recent report of the World Economy Forum “Our Shared Digital Future”, the following point was singled out from among its key observations: “Our existing institutions are struggling to respond effectively to the pace of change and its distributed nature”.³⁰ The centuries-old legal system has today come up against a challenge to its ability to remain a functional mechanism for regulating and resolving fundamental social issues and controversies.

The modern world, permeated with computer-aided and other new technologies, can no longer be described in the legal parlance based on classical rationalism. In the view of the world taken by today’s law, such categories as “equation” and “necessity” are gradually put on the back burners, whereas the notions of “likelihood”, “probability” and “chance” prove to be increasingly relevant. In fact, law is on the threshold of a systemic shift and transformation: “Today we are told that nature and society have never had and will never have any unalterable laws. Only time will tell how law makers and those who apply law will take this ‘welcome news’ from today’s science, and what conclusions they will draw”.³¹ Forward-looking law-making initiatives in the digital economy are those that make the legal system more flexible and adaptive.

1.1.3. Competition Law for the Fluid Modernity

Going back to the inequality problem and its connection with the new desirable legal framework, one has to start from the fact that the substance of laws is never confined to the natural laws of economic development. Law cannot be devoid of the value dimension, it is not an exact science.

In the digital economy, society may be very different, and as evidenced in practice, its spontaneous development tends to result in growing inequality. Therefore, reconfiguration of legal regulation, its adjustment to the dynamic processes of digitalization does not rule out but, on the contrary, makes a certain *teleological and value choice* inevitable. This means that the policy of law should rely on certain ideals and be developed in unity with economic and social policies.

Just as a hundred years ago, when humanity was faced with the challenges of fast track industrialization, the current stage of industrial revolution also raises its own grave existential questions. Extreme inequality risks launching a spiral of even more radical social stratification, which is capable, in turn, of eliminating the remaining social solidarity in global society.

The problem of ‘rigid’ law, which, according to U. Mattei and F. Carpa, has fallen into a ‘mechanistic trap’ and turned into a rather isolated system of rules, is very acute to all developing countries. A serious approach to reforming the legal system due to the challenges of the digital economy should, in our opinion, first of all suggest a revival of the legal ‘fiber’, a connection of the goals and objectives of economic development with legal

30 Our Shared Digital Future: Building an Inclusive, Trustworthy and Sustainable Digital Society, WEF Report, 2018, <https://www.weforum.org/reports/our-shared-digital-future-building-an-inclusive-trustworthy-and-sustainable-digital-society>

31 Мальцев Г.В. Социальные основания права. М., 2011. С.70. (G.V.Maltsev. Social Grounds for Law. M., 2011, p.70)

regulatory mechanisms. The most critical sphere of economic life at which the revival of the laws should be aimed is the sphere of diffusion of knowledge and information.

According to Thomas Piketty, “over the long period of time, the main force in favor of greater equality has been the diffusion of knowledge and skills”.³² At the same time, Piketty notes that the all-round spread of knowledge and technologies, which promotes greater equality, very often comes under pressure from forces that oppose such spread: “The crucial fact is that no matter how potent a force the diffusion of knowledge and skills may be, especially in promoting convergence between countries, it can nevertheless be thwarted and overwhelmed by powerful forces pushing in the opposite direction, toward greater inequality”.³³

Greater access to knowledge and advanced technologies, especially in developing countries is a powerful tool for overcoming inequality. Therefore, this is the most important goal in adapting legal norms to the needs of the digital economy.

In a recent report prepared by a team of economists led by Dean Baker and Joseph Stiglitz, they analyze the impact of the existing laws of intellectual property on the dynamics of world economic development. The authors conclude: “If the knowledge economy and the economy of ideas is to be a key part of the global economy and if static societies are to be transformed into ‘learning societies’ that are key for growth and development, there is a desperate need to rethink the current regime and to allow for a much less restrictive flow of information and knowledge”.³⁴

The practical implementation of this objective gives a special place to competition laws. The principal drafter of the first antitrust law in the world, the US senator John Sherman who caught the wave of the industrial revolution at the turn of the 20th century with his legislative initiative, was urging the US Congress to pass his bill with the following words: “Sir, now the people of the United States, as well as other countries are feeling the power and the grasp of these combinations, and are demanding of every Legislature and of Congress a remedy for this evil, only grown into huge proportions in recent times. They had monopolies and mortmains of old, but never before such giants as in our day. You must heed their appeal or be ready for the socialist, the communist and the nihilist”.³⁵

From that time flexibility became the key distinctive feature of antitrust regulation in all countries that passed relevant laws, but especially in those where the mechanism of competition law was initially developed to ensure effective performance of the capitalist system. Flexibility and focus on keeping the market competitive and preventing excessive concentration of market power determine the specifics of the mechanism for application of competition laws.

35 Congressional Records. 1896. Vol. 21.

Giuliano Amato, a former prime-minister of Italy and one of the leaders of the European Constitution project, describes this nature as follows:

“Antitrust law was, as we know, invented neither by the technicians of commercial law (though they became its first specialists) nor by economists themselves (though they supplied its most solid cultural background). It was instead desired by politicians and (in Europe) by scholars attentive to the pillars of the democratic systems, who saw it as an answer (if not “the” answer) to a crucial problem for democracy: the emergence from the company or firm, as an expression of the fundamental freedom of individuals, of the opposite phenomenon of private power; a power devoid of legitimation and dangerously capable of infringing not just the economic freedom of other private individuals, but also the balance of public decisions exposed to its domineering strength”.³⁶

The OECD report “Inequality: A Hidden Cost of Market Power” shows the fallacy of the view that competition policy should distance itself from the problem of wealth concentration and distribution.³⁷

From the very first days of antitrust law emerging on the wave of the US industrial revolution in the late 19th century, it was aimed in its core at balancing the capitalist system in order to remove social and economic tensions that were inevitably emerging against the background of dynamic growth and sweeping transformations. According to Joseph Stiglitz: “The changes in our economy and our understandings of the interplay between economics and politics necessitates a broader reach for competition policy than envisaged by the original advocates of antitrust law, and that this is especially so in developing countries and emerging markets”.³⁸ In a similar vein, the UN Digital Economy Report is urging for adapting existing competition law frameworks “to ensure markets remain competitive and contestable in the digital era”.³⁹

Unlike positive regulation aimed at the establishment of fixed rules, competition law is a flexible instrument of responding to problems and “bottlenecks” in economic development. In the context of the new technological paradigm, antitrust regulation should be designed above all to remove barriers to entering new markets and ensure broader access to key technologies and knowledge. It is the revival of law, its greater flexibility, that should be aspired by law-makers in developing countries willing to make their economies competitive in the 21st century.

In confronting growing global instability and inequality, solutions that strengthen the role of humans as actors in the digital economy may be among the most important. Humans should be provided with greater opportunities for self-fulfillment in the context of the growing “power of machines” and the power of those who mostly benefit from

the digital economy – Internet monopolies. From this point of view, Eleanor Fox quite logically insists that, “[a] vision of human rights that includes human economic welfare, in addition to the neoclassical economic view of aggregate economic welfare, is therefore necessary”.⁴⁰ Stronger legal positions of human beings, new opportunities provided thereto should become the basis for defining new legislative initiatives across the world.

A human-centric approach to the IP rights protection; promotion of open access and data commons regimes; more emphasize on ethical and sustainable development of technologies and digital services – all this can be included into the competition assessment matrix for the sake of more efficient responding to the major challenges of the digital era.

And finally, it is desirable to keep trying to establish an effective global regime for the protection of fair and equitable competition in the digital economy. Today such a global legal framework does not exist. The BRICS countries could make an important and practical contribution to a closer reach to this goal in the interests of sustainable social and economic development for all in the digital era.

1.1.4. Global Nature of Competition Regulation

The end of the Cold War, along with the established Washington consensus that the wealth of nations will result from trade and investment liberalization, privatization and deregulation,⁴¹ changed the perceived nature of the global marketplace and opened doors for new opportunities, including for ones “in the area of competition law.”⁴²

Along with geopolitical changes, another important shift well symbolized by the Internet had a transformative impact on the global marketplace by virtue of new communicative and information technologies. This transformation changed the perception of the global marketplace, allowing some commentators to say that, “the Web-enabled playing field” rendered the world flat.⁴³

The idea of a free and open global market became extremely powerful in the 1990s and spread around the world. The rise of this new perception provided the momentum for institutional and legal changes. As Jon Hanson put it, “In brief, what changed was the meta script,”⁴⁴ which forms the ideas, concepts and conclusions comprising the first and “highest” level of the law”.⁴⁵

“What we may be witnessing is not just the end of the Cold War, <...>, but the end of history as such: that is, the end point of mankind’s ideological evolution and the universal-

ization of Western liberal democracy as the final form of human government.”⁴⁶ – was famously proclaimed by Francis Fukuyama. This neo-liberal agenda, like Milton Friedman’s assertion that, “the operation of the free market... foster[s] harmony and peace among the people of the world,”⁴⁷ and focus on consumer welfare, triggered a broader question – why is it that competition law calculus does not include consumer welfare of other nations?

It is quite consistent with the faith in a free and open market, which, according to Richard Posner, “works best to achieve the common goals of most people in the world”⁴⁸ to consider the consumer demands as just consumer but not political actors. Chris Noonan insists that, “[t]he process [towards global competition law] should start by building a consensus among states that the long-term interests of all states would be advanced if international competition law had the overall objective of maximizing global consumer welfare.”⁴⁹

But it did not happen. Although the global consumer welfare prescription is based on the ideological paradigm promoted as a part of the liberalization project, but the practical interests of the major states did not allow it to become a normative prescription in the legal framework of the global economy. Neither in the framework of the International Trade Organization in the 1940s, nor in the context of the United Nations in 70s and 80s, nor under the World Trade Organization’s umbrella, the global competition law regime did not play out.

But a direct outcome of those numerous initiatives to establish a global cohesive legal regime for economic competition in the world has led to a particular role for competition law to play. Dissemination of competition regimes around the world and adoption of competition values by most of the world jurisdictions and international organizations have led to a series of effects making competition law an important factor in regulating the global economy distinct from other legal regimes (primarily of ex-ante regulations) also not unified under the international laws but not having such international recognition as competition law. All leading countries recognize the importance of competition and allow for various forms of market intervention to protect competition. Also, the principle of competition protection is central to a whole range of key international agreements. For example, the Agreement on Trade Related Aspects of Intellectual Property Rights within the WTO directly provides for national states to limit the rights of intellectual property in order to protect competition.

Competition law receptive to international cooperation strongly improves the effectiveness of its application. For instance, if BRICS countries or those of other blocs of emerg

ing economies take coordinated decisions on global monopolists, such decisions will be impossible to ignore.

These special features add more regulatory impact on global economic processes to countries that otherwise carry little weight in the world economy and are unable for this reason to set effective global market rules. Considering almost global acceptance by the major jurisdictions of the value of competitive process, competition law makes it possible for even small economies to influence the global processes of economic life in the new technological paradigm if they impose some nuanced restrictions on the global digital players in line with competition law analysis.

The range of tools for competition protection is quite broad and can be adapted to solve key objectives of fixing “bottlenecks” of the global digital economy, namely, ensuring access to the key elements of global infrastructure of the digital economy – above all to data and knowledge. It is apt to wonder would it be much a stretch to say that competition law is a relatively unique mechanism of the regulatory impact of small and medium-sized economies on global economic processes unfolding in the digital economy.

Evolving BRICS cooperation in the sphere of competition law and policy can provide a new hope for the global economy. This cooperation is aimed to embrace the peculiarities of globalization in its current phase. What is common for the BRICS jurisdictions is that they are all in search of a solution allowing to shortcut the developmental track. This experimentalist energy and creativity being the main characteristics of the group are extremely important for the current phase of global economic development. It is not only an institutional structure of the global order that is in transition but also the very nature of the global marketplace. The key focus of the new global competition policy should be the facilitation of openness among global networks and value chains through the reduction of the manipulative and exclusionary potential of digital platforms. The BRICS cooperation has an important role in making the global marketplace both fairer and more equal as it has an ability to promote a form of competition encouraging a broader dissemination of knowledge and advanced technologies that would cover the largest percentage of the world population, while eliminating barriers imposed on the global flows of innovation by both the global technological monopolies and cartel-like technological joint ventures burgeoning within their “walled gardens” at the expense of the excluded consumers and entrepreneurs around the world.

In the following chapters of this report, we explore in more details how the digital economy challenges can be converted into policy solutions and actual steps in improving competition law practice and legislation in the BRICS countries. The UN Digital Economy Report concludes that “there is a growing need for competition policy to be set and enforced within regional or global frameworks”⁵⁰. We hope that the timely initiative of the BRICS countries to further advance cooperation in the competition law and policy domain can address this need.

50 The Digital Economy Report 2019, UNCTAD, P. 138

1.1.5. The emergence of digital financial capitalism

One of the crucial hypotheses of this report is that financialization lays at the center of the shift toward digital or informational capitalism: the term denotes the focus of modern capitalism on the predominance of the shareholder-value perspective, according to which firms and corporations are largely accountable for maximizing the short-term benefits of their shareholders through IPOs, collective ownership, stock buybacks, and other financial instruments. To accomplish this, starting in the 1980s, firms reversed from the allocation regime of 'retain and reinvest', where companies invested their revenues in job-creating innovations in organization and technology, to a regime of 'downsize and redistribute' that is focused on the allocation of revenues to shareholders. Lazonick traces these developments in terms of a shift from an 'old-economy business model' (OEBM) to 'new-economy business model' (NEBM)⁵¹. This shift, according to Lazonick, took place at different levels and on various dimensions, including models and practices of technological innovation, corporate governance, and capital investment, particularly in the high-tech world of Silicon Valley.

In brief outline, the adoption of open-systems standards by major players of the computer industry led to the weakening or abandonment of internal R&D within major corporations in favor of patenting, cross-licensing, outsourcing, and the takeover of start-ups. Technically, this was accompanied by the design and development of modular components that were manufactured by offshore companies and vertically integrated in niche markets. Financially, the shift was made possible through the rise of organized venture capital, cushioned by large investment from large retirement and pension funds (see Table 1.1.). These had important implications on the nature of work and led to important changes in the patterns of employment in these large corporations from the late 1970s, a process that accentuated with the development of personal computing and the Internet in the 1980s and 1990s.

Table 1.1. Old Economy Business Model vs New Economy Business Model

	OEBM	NEBM
Strategy, product	Growth by building on internal capabilities; business expansion into new product markets based on related technologies; geographic expansion to access national product markets.	New firm entry into specialized markets; sale of branded components to system integrators; accumulation of new capabilities by acquiring young technology firms.
Strategy, process	Corporate R&D labs; development and patenting of proprietary technologies; vertical integration of the value chain, at home and abroad.	Cross-licensing of technology based on open systems; vertical specialization of the value chain; outsourcing and offshoring.
Finance	Venture finance from personal savings, family, and business associates; NYSE listing; payment of steady dividends; growth finance from retentions leveraged with bond issues.	Organized venture capital; initial public offering on NASDAQ; low or no dividends; growth finance from retentions plus stock as acquisition currency; stock repurchases to support stock price.

51 W. Lazonick, *The New Economy Business Model and the Crisis of U.S. Capitalism*, (2009) 4(2) *Capitalism and Society*, Article 4.

	OEPM	NEPM
Organization	Secure employment: career with one company; salaried and hourly employees; unions; defined-benefit pensions; employer-funded medical insurance in employment and retirement.	Insecure employment: interfirm mobility of labour; broad-based stock options; non-union; defined-contribution pensions; employee bears greater burden of medical insurance.

The emergence of the Fintech industry provides an illustration of the complex interplay between the processes of datafication and financialization and the emergence of specific forms of digital competition that may look different from the competitive process in the 'Old Economy'.

1.1.6. Case study: Fintech and banks in the Digital era

'Fintech' became a buzzword several years ago with the emergence of a large number of start-ups offering innovative financial services and promising to re-shape the future of finance.

Fintech is an abbreviation for Financial Technologies and refers to organizations where 'financial services are delivered through a better experience using digital technologies to reduce costs, increase revenue and remove friction'.⁵² The business models based entirely on digital products set them apart from traditional banks whose services might be similar but originally lacked a digital component.⁵³

There are certain difficulties in defining the exact scope of Fintech. However, there are easily identifiable product clusters, such as payments, lending/crowdfunding, deposits, financial planning, trading and investments, insurance, digital currency, wealth and asset management, enabling technologies and infrastructures.⁵⁴ This reflects the gradual diffusion of Fintech into areas that have been a domain of traditional banking institutions (such as lending), as well as the emergence of completely new areas such as the trading of digital assets.

Over recent years, investment in Fintech has been increasing exponentially and reached \$111.8 billion in 2018⁵⁵ (compared with \$19.9 billion in 2014),⁵⁶ more than doubling during 2018 alone. Though the information on the overall market volumes of Fintech activities is scant, the indicators related to specific markets show its significant growth. Thus, the volume of marketplace lending has increased from

56 '2018 is Already a Record Year for Global FinTech Investment' (11 July 2018) <https://fintech.global/2018-is-already-a-record-year-for-global-fintech-investment/> accessed 31 March 2019.

less than \$100 billion in 2015 to \$300 billion in 2018.⁵⁷ The Cambridge Center for Alternative Finance estimated the total volume of online alternative finance in the EU to be EUR 7 671 million as of 2016, which is 41 % higher than in 2015.⁵⁸

The Fintech adoption level has been also growing steadily. Thus, the average percentage of digitally active consumers using Fintech services reached 33% in 2017, compared to 16% in 2015.⁵⁹ The Fintech adoption level is considerably higher across emerging markets (46%).⁶⁰ This can be explained by the high level of tech literacy, internet and mobile penetration on the one hand, and the vast proportion of financially underserved population on the other hand.⁶¹ The examples of China and India with the highest rates of Fintech adoption⁶² demonstrate the main strength and weakness of Fintech. Where there is a vast proportion of unbanked population, Fintech companies are able to gain momentum and scale up quickly (leading to the potential rise of large companies like Ant Financial).⁶³ Meanwhile, in the well-served markets, like Europe, Fintech companies are focusing on improving user experience by complementing the existing offerings of traditional financial institutions⁶⁴ and often struggle to build scale on their own.⁶⁵

At the outset, there were two possible ways for the development of Fintech. The first one was to challenge incumbent financial institutions and to eat away their market shares (*disruptive path*). The initial ambition of Fintech was nothing less than 'a democratic revolution for all who use financial services'.⁶⁶ For example, alternative online banking first emerged with an aspiration to replace traditional

(Speech at the Lord Mayor's Banquet for Bankers and Merchants of the City of London at the Mansion House, London, 16 June 2016) <https://www.bankofengland.co.uk/-/media/boe/files/speech/2016/enabling-the-fintech-transformation-revolution-restoration-or-reformation> accessed 24 March 2019.

banks.⁶⁷ But except for some underserved sectors, most Fintech companies have shifted to building partnerships with incumbent banks as they struggled with scale and customer adoption (*collaborative path*).⁶⁸ Likewise, traditional financial institutions have noticed the opportunities arising from the emergence of new technologies and, first threatened by potential competition from Fintech start-ups, quickly switched to use them as a 'supermarket' for capabilities with the view to integrating them into the traditional banks' ecosystem.⁶⁹ Partnerships between traditional financial institutions and Fintech is becoming more and more common and take various forms.⁷⁰

In order to understand the competition implication of various business strategies adopted by traditional banks and Fintech, this study considers both *intra-platform* and *inter-platform competition*. Many experts have emphasised the ongoing transitions of the financial industry from product to platform competition, with the rise of financial platforms set to only accelerate in the future.⁷¹ The World Economic Forum identifies platform rising among eight disruptive forces that have the potential to shift the competitive landscape of the financial ecosystem with the power being transferred from financial services providers to the owner of the customer

70 For example, Alessandro Hatami has identified four models of the collaboration between traditional banks and Fintech: channel model when the bank helps the Fintech to sell its products to the bank's customers (e.g. the partnership between JPMorgan and OnDeck); supplier model when the bank engages with the Fintech as if it were a supplier (e.g. the collaboration between Bud and HSBC's First Direct); satellite model where the bank acquires the Fintech start-up, but leaves it relatively independent (acquisition of Nickel by BNP Paribas), and classical merger model where the acquired Fintech is integrated and rebranded within the bank (the acquisition of Final by Goldman Sachs' consumer bank Marcus), see Alessandro Hatami, 'Bank & FinTech Collaboration Models' (14 August 2018) https://medium.com/@a_hatami/bank-fintech-collaborations-how-big-banks-plan-to-stand-up-to-the-big-tech-challenge-24eea57db095 accessed 20 May 2019.

interface.⁷² The platform's goal would be to develop a financial services ecosystem with different components developed by different firms, then combined and sold via the common customer interface. This reflects the digital trend of commoditization of the banking services replacing the universal banking model,⁷³ where the various sectors of financial activities are unbundled and specialized suppliers deliver financial products as commodities.⁷⁴

In these circumstances, the *intra-platform competition* (i.e. competition between participants of the platform to capture a greater share of the value generated by the platform) becomes of particular importance.⁷⁵ The 'eco-system manager' or 'platform architect' sets the rules, controls the underlying platform technology, and determines who can participate in the platform.⁷⁶ This allows him to capture the lion's share of the whole profit. From the outset, the traditional banks are in a better position to gain the architectural advantage within the platform business model compared to Fintech. Among the primary reasons are high entry barriers in the industry,⁷⁷ network effects,⁷⁸ strong brands and trust-based relationships of incumbents and customers reluctance to switch to Fintech providers.⁷⁹ A significant entry barrier is the traditional banks' hold on the financial infrastructure, most notably the access to customer accounts.⁸⁰ These industry-specific factors might have driven Fintech to take the collaborative path, instead of unleashing the full disruptive potential of new technologies.

This lack of competition between incumbents and new entrants has presented a continuous concern for regulators, who considered Fintech as an important source of innovation and competition in the industry.⁸¹ Consumers also can benefit from increased competition between banks and Fintech companies as it can lead to disintermediation of existing value chains, lowering prices of financial services,⁸² improving customers experience and promoting financial inclusion in underserved markets.⁸³ To bring about the full potential of financial innovation, Fintech companies need to scale up effectively to compete with incumbents. This explains why

policy makers and competition authorities around the globe consider a level playing field for Fintech companies and traditional financial institutions as a *sine qua non* of getting the best value for customers from Fintech.⁸⁴

In search for this level playing field, the regulators first turned their eye to the main source of the banks' architectural advantage – the customer accounts. Blocking or limiting access to customer accounts (even given the customer's explicit consent) significantly impedes the Fintech firm's ability to provide innovative services. For instance, mobile payments or aggregation of banking products⁸⁵ require linkage to a bank transactions account. The bank holding all the account information and technical access to the account can leverage this to keep potential competitors away from these lucrative markets. Denying the Fintech's access to customer accounts as crucial gateways of traditional banking activities increases the probability of exclusionary conduct on the part of banks and gives them the upper hand in the fight for architectural advantage.⁸⁶ As the COO of Fidor Bank put it: '[B]ank accounts are the last mile. Finance has had a hold on that, and will continue to leverage it'.⁸⁷

The recent EU and UK regulatory initiatives are intended to provide certain categories of Fintech companies with access to banking infrastructure. Thus, the second EU Payments Service Directive (PSD2), approved by the European parliament in 2015, obliges EU banks to provide open-APIs⁸⁸ for payment services.⁸⁹ The directive requires banks to provide third party providers (TPP) access to: (i) *account information* which allows a payment service user to have an overview of their financial situation at any time; and to (ii) *payment initiation services* which allow consumers to pay via simple credit transfer for their online purchases via TTP software.⁹⁰ The similar Open Banking initiative in the UK followed the Competition and Markets Authority investigation into retail banking⁹¹ which found that the incumbent banks

‘d[id] not have to compete hard enough to win and retain customers’ compared to new entrants.⁹² It required the nine biggest UK banks⁹³ to allow licensed start-ups direct access to their data including detailed account information.⁹⁴ By the end of 2018 there were already more than 80 third party providers registered with the Financial Conduct Authority to provide either payment initiation or account information services and up to 17.5 million API calls per month.⁹⁵ However, the implementation of the PSD2 in EU has taken more time. By September 2019 it should finally land as the banks are expected to have implemented dedicated APIs for third-party providers in compliance with the European Banking Authority’s Regulatory Technical Standards (‘RTS’).⁹⁶ Some surveys indicate though that the European banks generally have failed to prepare for this deadline with the RTS compliance rate slightly over 50% on average.⁹⁷

PSD2 and Open Banking are largely beneficial for intra-platform competition, as they enable Fintech providers ‘to engage directly with and add value to customers’⁹⁸ without relying on the banks’ consent to grant them access to customers’ current accounts. This removes an important bottleneck in the financial services value chain. Access regulations have potential to further disintermediate the financial sector through unbundling the financial services value chain and thus promoting competition in these unbundled segments.⁹⁹ On the other hand, these initiatives may nudge banks to move quicker to the platform model where the services providers bring together various customer groups into one ecosystem managed by the bank. This mostly depends on the strategy chosen by banks – whether they consider the open APIs requirement as an impediment to their existing business model or as a potential ‘extension to the bank-as-a-platform’ concept¹⁰⁰ and an opportunity to capture an even bigger share of the customers market.¹⁰¹

Having said that, the access regulations might have inadvertent implications for *inter-platform competition*, i.e. the competition for becoming the industry dominant platform or the “industry architect”.¹⁰² Thus, Miguel de la Mano and Jorge Padilla point out in their paper that PSD2 is asymmetrical, as it enables the flow of crucial data only from banks to TTPs, but not the other way round. This can potentially give unfair advantage to Big Tech companies which can benefit in a direct or indirect way from the access to this raw data without having to invest in the relevant IT infrastructure.¹⁰³ Therefore, these regulations may shift the advantage in the industry architectural fight from the Big Banks to the Big Techs.

To grasp the full implication of the last argument, one needs to delve carefully into analysis of the inter-platform competition and the role played by Big Tech companies in financial markets. Big Tech are defined as global technology-based firms with widespread adoption across geographies.¹⁰⁴ These include Google, Apple, Facebook, and Amazon (GAFA) in the Western hemisphere and Baidu, Alibaba and Tencent (BAT) in Asia. Many Big Tech companies have already ventured into financial services, starting with payments and lending related to their principal platform offerings.¹⁰⁵

Among GAFA, Amazon is well-known for its attempts to unbundle the financial value chain and continuous investments in multiple areas of financing (see Figure 1.4.).¹⁰⁶ Amazon’s broader strategy involves ‘building a low friction payments service to attract customers online’¹⁰⁷ to ultimately increase participation (both from buyers and sellers) on its platform. Since the launch of its first payment service “Pay with Amazon” in 2007, Amazon has ventured into mobile payments and digital wallets (Amazon Pay and its predecessors), cash deposits (Amazon Cash, launched in 2017), B2B lending (Amazon Lending, launched in 2011), B2C lending (Amazon Prime credit cards, the first card launched in 2015), insurance (Amazon Protect, launched in 2016).¹⁰⁸ Amazon plans to further expand into checking accounts,¹⁰⁹ mortgage lending,¹¹⁰ home and health insurance.¹¹¹ Interestingly, each of its fi-

financial propositions leverages the network effects and Amazon's vast consumer base in other markets. For instance, home insurance might be offered in conjunction with its home devices, such as Alexa; Amazon Prime cards first leveraged the strong presence of Amazon in e-commerce (Amazon Prime programme) and then expanded beyond e-marketplace as well as to non-Prime customers (Amazon Visa Credit Card).¹¹² In general, the long history of Amazon's expansion into finance demonstrates that it is serious about gaining a hold of the financial market and transforming it into a completely new digital experience (Figure 1.1.).

Figure 1.1. Amazon and the unbundling of the bank

Source: CBInsights.

Another salient example of the successful foray into financial markets is the Chinese tech giant Tencent. Its most significant innovation was coupling mobile payments with the online messaging and social media platform, WeChat.¹¹³ Due to a largely unbanked population in China, Tencent's innovations like WeChat Pay and QQ Wallet quickly gained momentum with WeChat payments having risen to \$1.2 trillion in 2016 from less than \$11.6 billion in 2012¹¹⁴. To further engage users in its

ecosystem, Tencent launched wealth management tools (Li Cai Tong and Ling Qian Tong, in 2014), a B2C lending platform (WeiLiDai, 2015) and a B2B lending platform (Wei Ye Dai, 2017), an insurance agency platform (WeSure, 2017), and two online pension funds (2018).¹¹⁵ In 2015 Tencent even set up the chartered bank, WeBank, which is considered the first private Internet bank in China.¹¹⁶ Thus, Tencent has gained complete presence throughout all the retail banking sector, driving all its WeChat user base towards its own financial ecosystem.

There are more examples like this related to other Big Techs, including Google, Apple, Alibaba, and Facebook. Virtually all of them tried to launch financial products and achieved definite success, especially among millennial customers.

This is a clear sign that few dominant platforms or ‘industry architects’ are likely to emerge in the financial industry. Industry architects shape how the industry evolves in order to ‘capture a disproportionate amount of the surplus value created by the innovation’.¹¹⁷ These are the firms with superior performance that can control ‘bottlenecks’ and ‘leverage their position of strength over all other companies’.¹¹⁸ The battle over who becomes the financial industry architect will define who ultimately shapes the further development of the financial sector.

The Big Tech companies have a good chance to win this battle because they already possess several strategic advantages over both traditional financial institutions and Fintech. First, Big Tech companies have amassed rich customer data in other markets where they have already gained a strong presence (e.g. social media, online marketplace, etc.). These data are much more vast and, importantly, update almost instantly, than any data owned by a single bank let alone a Fintech start-up. On top of that, Big Techs benefit from emerging technologies, such as Big Data, AI, predictive analysis,¹¹⁹ that constitute further architectural advantage as it allows the setting of standards for the whole ecosystem.¹²⁰ Big Techs can leverage their strong position, revenues and consumer network in adjacent markets to gain a foothold in the financial sector. Importantly, unlike nascent Fintech companies, Big Techs have already strong brand recognition and ‘are generating a level of trust previously reserved only for traditional banks.’¹²¹ Finally, they are still subject to much looser (if any) regulations compared to traditional banks. By adopting a business model of ‘intermediaries’, they avoid burdensome regulations but can hold the grip of the most important customer interactions. In fact, Amazon attracts millions of dollars of customers’ money through Amazon Cash without the need to

comply with the capital requirements as regulated banks do.¹²² Alibaba's Yu'e Bao fund is the world's largest money market fund, with \$165.6 billion under its management, still loosely regulated.¹²³ These are examples of asymmetrical regulation that can place banks in artificial disadvantage relative to Big Tech platforms.¹²⁴

In this situation, access regulations such as PSD2 and Open Banking may miss the mark, as they do not take into account an important component of the competitive triad, namely – the Big Tech companies. According to PSD2, traditional banks are obliged to provide access to their customer data to all authorised competitors (including Big Tech platforms) free of charge. In fact, in the view of PSD2 fully entering into force in September 2019, many Big Tech companies have hurried up to obtain the so-called 'e-money' license in the European Union, including Amazon (May 2011, Luxembourg)¹²⁵ and Facebook (back in October 2016, Ireland)¹²⁶ among the first, followed by Google (December 2018, Lithuania and January 2019, Ireland)¹²⁷ and Alipay (January 2019, Luxembourg).¹²⁸ This license will allow them to tap into the customer data collected by the banks and provide 'one-click' payment and account information aggregation services directly to consumers.

On the other hand, Big Tech companies are not obliged to open up their customer data to competitors – to the contrary, under GDPR they 'will de facto retain economic sovereignty over the data of their customers'.¹²⁹ This has the potential to exacerbate the data disparity between banks and Big Tech platforms and lead to traditional banks being 'enveloped' by the tech giants, thus losing the fight for architectural advantage.¹³⁰ The banks and smaller Fintech competitors might end up as mere suppliers of unbundled financial products with the market power transferred to owners of the customer experience (i.e. digital platforms).¹³¹ In fact, Big

Tech platforms deny their ambitions to become the likes of banks. What they want is merely to offer financial services to their customer base to increase participation in their digital ecosystems¹³² – ‘building a bank for [themselves]’,¹³³ or more precisely to their vast clientele. This reveals Big Tech’s ambition to occupy the most profitable position in the financial eco-system to extract most of the value generated by other levels without bearing the costs of regulatory compliance and relevant operation, security, and data protection risks. In the face of these challenges, Fintech and traditional banks have even stronger incentives to cooperate rather than compete against each other in order to morph into the modern digital platforms and stay atop the competition with Big Tech.¹³⁴

What are the implications for competition and regulatory policies? One of the options proposed to ensure a true level playing field is to introduce the reciprocity of data sharing obligations between banks and digital platforms.¹³⁵ This means that ‘[p]latforms above a certain size would have to grant access to others, including traditional banks, to a subset of their data’ (with the data subject to consent, of course).¹³⁶ This is in line with the general move to prescribe a wider access to the data collected by the digital platforms when such data is instrumental to compete and foster further innovation in the relevant or adjacent markets, especially when data collection happens incidentally and without special investment.¹³⁷ Though unclear how it would be implemented in practice, this suggestion rests on the important premise – the data sharing obligations should apply to all firms reaching the certain threshold regardless of the sector where they are active or their regulatory status. This ‘agnosticism towards the business model’¹³⁸ means that competition authorities and regulators should not look solely at the business model, but at the competitive impact it has on a relevant market, avoiding regulating only some of the players and skewing the competitive environment in these markets.¹³⁹

However, to effectively compete in financial markets, Fintech start-ups might require not just a one-time access to the data collected by the Big Tech platforms, but continuous data interoperability meaning real-time access to the data, normal-

139 *ibid.*

ly through privileged APIs.¹⁴⁰ This basically means extending the perimeter of PSD2 requirements to digital platforms. The scope of such extension is still unclear (for example, whether it should be applied only to platforms already active in the financial markets or any platforms owning the data that is essential for Fintech to provide the complimentary products to the platform's users). It is also unclear whether such interoperability should be provided only to Fintech companies or both Fintech companies and traditional banks. Miguel de la Mano and Jorge Padilla argue that the data sharing obligation through open API's should be applied to digital platforms vis-à-vis not only Fintech, but also vis-à-vis traditional banks, as digital platforms pose the largest threat to competition in financial markets.¹⁴¹ In addition, considering the constant confluence between Fintech and traditional banks, it might be difficult to separate the two. Also in line with the 'business model agnosticism' it might be undesirable to discriminate between competitors using different business models. On the other hand, some authors express concerns that if leading banks manage to benefit from the big data and network effects provided by the new digital business models (and potentially by open access to the digital platforms' data storages), these banks might gain even bigger market shares and pose threat to financial stability further exacerbating the "too-big-to-fail" problem.¹⁴² In this scenario, any type of access regulation (asymmetric and symmetric) might be a double-edged sword requiring careful assessment of its impact on the competitive conditions in the market.

Alternatively, rather than relying on the sector-specific regulations (like PSD2), the access to data amassed by dominant digital platforms can be mandated by competition authorities based on Article 102 TFEU and its likes in the national legislations. When dominant, data-rich companies refuse to grant other firms access to their data, provided that the access to such data is indispensable to compete effectively in the relevant or neighbouring markets and there is a real danger of further entrenchment of the market power, competition authorities should treat this as abuse of the dominant position under Article 102 TFEU. However, this involves careful balancing between the need to protect the investment incentives of dominant firms and ensuring that the markets remain contestable and the competition for the market is protected.¹⁴³ The benefit of such an approach is that it is context-sensitive and allows to give or deny access to the customer data of the dominant firms based on the competitive dynamics of the market at hand, avoiding potential inadvertent externalities produced by the access regulations. Having said that, the assessment of market power in the financial markets is very difficult due to the diversity of business models and potential sources of market power.¹⁴⁴ Identifying data-related exclusionary practices in financial markets also requires

144 A. Fraile Carmona and al. (n 58) 48.

further elaboration of traditional theories of harm. These might include, for example, cross-usage of the data sets by big tech companies,¹⁴⁵ where a digital platform can use its privileged access to data obtained in one activity to leverage its position in the provision of other services, such as Fintech services.

Another problem might arise where the anonymous access to individual-level data or aggregated data is required to effectively compete in financial markets. Unlike PSD2 data sharing requirements, this involves access to the pseudonymized/anonymized and aggregated data of many users,¹⁴⁶ for example, to make accurate predictions of the user behaviour in order to deliver better services. One example might be a Fintech start-up that analyzes patterns in user behaviour to predict their chances to default on loan repayments and then rent out this solution to larger financial institutions.¹⁴⁷ The recent FSB report has pointed that 'banks and other lenders are increasingly turning to additional, unstructured and semi-structured data sources, including social media activity, mobile phone use and text message activity, to capture a more nuanced view of creditworthiness, and improve the rating accuracy of loans.'¹⁴⁸ Such AI and machine learning applications in Fintech crucially depend on the availability of Big Data that allow to find statistically meaningful patterns and deviations and predict the riskiness of loans, investment portfolios, as well as to make pricing decisions and detect financial crimes, money laundering and fraud.¹⁴⁹ There is already a plethora of vendors that provide machine learning for financial market participants, based on publicly available sources, such as news, market analytics, etc. However, it is clear that firms which have access to larger data sets get strategic advantage in making better predictions and delivering better services.

According to the recent EU Commission's Report 'Competition Policy for the Digital Era', in such a scenario the access to data can be granted when it could be demonstrated that no substitutes exist in the market (the data is not available from data analytics providers or cannot be collected by a Fintech firm on its own) and the relevant data is indispensable to compete in the complimentary markets where a data controller is dominant.¹⁵⁰ When it comes to personal data, the situation is complicated by the GDPR requirements. In such cases, 'access to data for specified purposes and specified acts of processing may be mandated by a competition authority based on an interest balancing (Article 6 lit. f GDPR) or based on Article 6 lit.

145 A. Fraile Carmona and al. (n 58)

148 Financial Stability Board, 'Artificial intelligence and machine learning in financial services: Market developments and financial stability implications' (01 November 2017) 12, <http://www.fsb.org/wp-content/uploads/P011117.pdf> accessed 15 April 2019.

149 *ibid.*

150 Jacques Crémer, Yves-Alexandre de Montjoye, Heike Schweitzer (n 137) 101-104.

e GDPR which, *inter alia*, allows processing that is necessary for the performance of a task carried out in the public interest'.¹⁵¹ It should be noted that access to data necessary for the purpose of training algorithms for uses completely unrelated to the markets where the data owner is active cannot be granted based on competition law.¹⁵² The specific regulatory regime might be needed to this end.

Legal cases on granting access to the data and payment infrastructure in financial markets are yet to emerge. It is also too early to draw conclusions on the outcomes of the access regulations, such as PSD2 or Open Banking. It is clear, however, that continuous scrutiny of the competition dynamics evolving between Big Tech, banks and Fintech firms is needed to ensure that data sharing obligations are used to invigorate both inter-platform and intra-platform competition and not for tacit collusion or increasing the market power of some players. As data is the source of competitive advantage, the combination of big data possessed by banks and digital platforms can potentially foster creation of dominant platforms in financial markets. Therefore, the rise of big platforms and the challenges arising from network effects which create significant barriers to entry remain the main competition concern in financial markets.¹⁵³ As the battle for gaining architectural advantage over the financial industry is ongoing, competition authorities should strive to promote competition on merit between various platforms and business models as well as fair and non-exclusionary practices within the vertical value chains. To this end, market monitoring and careful assessment, rather than introducing new sector-specific regulations might be a desired short-term solution.

As described above, the financial industry currently undergoes significant transformation, with the advent of agile Fintech competitors (referring to companies delivering financial services exclusively through digital technologies), transition to the platform business model and the threat posed by Big Tech being the most important trends. Competition authorities around the globe generally assess Fintech as a positive trend and expect Fintech to apply continuous competitive pressure on incumbent financial institutions for the benefits of consumers. However, in more developed economies, Fintech companies opt for cooperation with established financial institutions rather than challenging them, while in emerging economies with the high degree of financial exclusion (e.g. China and India) the disruptive potential of Fintech is much more evident.

Access regulations, such as the second EU Payment Services Directive and Open Banking in the UK, have potential to reduce entry barriers for Fintech companies and allow them to compete on a par with large financial institutions. However, the emergence of Big Tech companies (Google, Apple, Facebook, Amazon, Alibaba, etc.) offering a whole array of financial services to their customers changes the competitive dynamics in financial markets. In the future, the battle for becoming

151 *ibid*, 104.

152 *ibid*, 98.

153 A. Fraile Carmona and al. (n 58) 13; Rory Van Loo (n 53) 250.

a dominant financial platform that holds a grip over the customer interface might become definitive in the further development of Fintech and financial industry in general.

Therefore, competition authorities need to analyse carefully the interactions within this competitive triad (traditional banks, Fintech and Big Tech) and monitor market developments in order to identify tipping points and potential bottlenecks that might lead to the emergence of dominant financial platforms and the exclusion of competitors from the market. Extending a perimeter of access regulations to the tech giants and obliging them to open the access to their data might represent one solution to this concern. Imposing on dominant platforms an obligation to share their data under Article 102 TFEU and its likes is another option to tackle exclusionary practices in finance. In any case, protecting competition in modern financial markets requires careful recalibration of traditional competition law tools and approaches.

1.2. Consequences of digital competition for economic actors and the intangible economy: empirical insights

1.2.1. Country-level effects

The BRICS countries already occupy a significant place in the global digital system, despite significant differences within the group. China takes the lead in the global digital sector. It is the only country not only among the BRICS countries, but globally – with companies in the top 20 internet firms by market valuation, along with U.S. firms (Figure 1.2.).

Figure 1.2. Top 20 Internet leaders by market valuation, 2018

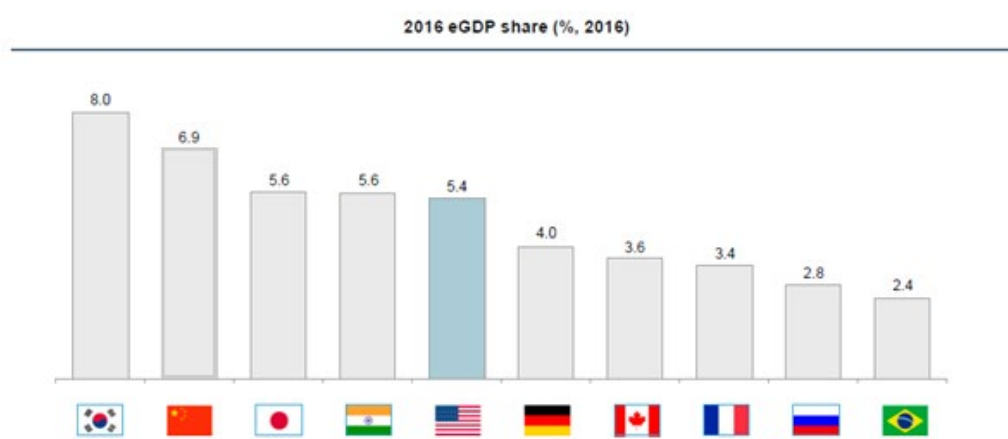

Source: <https://www.visualcapitalist.com/visualizing-worlds-20-largest-tech-giants/>

Other BRICS countries have their own digital leaders. Forbes Top 100 Digital Companies list¹⁵⁴ also includes, in addition to 16 companies from China, two companies from India and one from South Africa.

The BRICS countries are among the largest in the world in terms of size of their digital economy. Of the 10 countries with the highest eGDP¹⁵⁵ share four places are taken up by BRICS countries. Two of these countries – China and India – have a higher eGDP share than the U.S. (Figure 1.3).

154 <https://www.forbes.com/top-digital-companies/list/#tab:rank>

155 eGDP (Gross Domestic Product) is an indicator proposed by the Boston Consulting Group (BCG) that calculates digital/internet-related expenditure in private consumption, investment, government expenditure and net export.

Figure 1.3. Top 10 countries with highest eGDP share in 2016

Sources: (Cheng, 2017)¹⁵⁶, BCG

The number of internet users – actual and potential – makes the BRICS countries' markets very attractive for global digital players operating in e-commerce, social networks, search, etc. (Figure 1.4.).

Figure 1.4.: Countries with the highest number of internet users as of March 2019 (in millions).

Source: Statista

Thus, the BRICS countries are currently in the forefront of global digital competition.

1.2.2. Region-level effects: BRICS

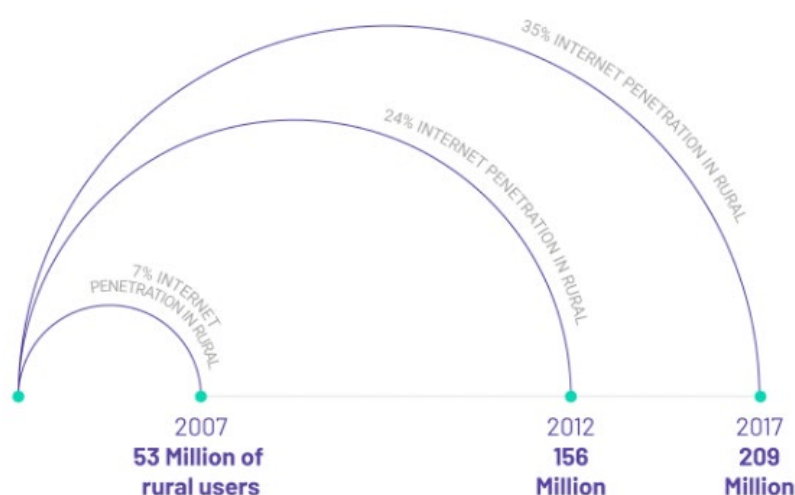

In terms of regional effects of digital competition in the BRICS countries the main barrier to an even distribution of gains between regions is the digital divide within their vast

¹⁵⁶ Cheng W. (2017) The Tale of the Digital Economy in China. Presentation for the 5th IMF Statistical Forum, November 16, 2017.

territories, namely between rural and urban areas. This problem is especially important for China and India. In 2015, half of the world's unconnected population (2.2 out of 4.3 billion people) resided in China and India.¹⁵⁷ However, the countries have targeted that divide and have made tremendous strides towards narrowing it in the last few years.

The latest statistics from India, characterized by the lowest internet penetration rate among the BRICS countries, indicate that while the number of urban users grew 7% in 2018 compared to 2017, the number of rural users increased 35%, reaching 251 million users (expected to reach 290 million in 2019). Consequently, the penetration rate in rural India reached 25% in 2018.¹⁵⁸ China has also been active in increasing internet penetration rate in rural regions. The progress between 2007 and 2017 is presented in Figure 1.5 .

Figure 1.5.:Internet penetration in China's rural regions, 2007-2017

Source: China Internet Report 2018

In 2017, Brazil exhibited a 74.8% access rate for urban areas and a 39% for rural areas. Regional disparities exacerbate this scenario: the less connected municipalities in Brazil are in predominantly rural areas of the North and Northeast regions.¹⁵⁹ While in general high prices for internet access ranked as the main reason for lack of connectivity, the lack of infrastructure is listed as a key reason for absence of internet access in the rural households compared to urban households.

South Africa is also characterized by high variance in internet access between provinces. Gauteng has the highest rate with 72.2% of its people having online access, while the Western Cape is second with a 68.5% rate. At the other end of the spectrum Limpopo

157 West D.M. (2015) Digital divide: Improving Internet access in the developing world through affordable services and diverse content. Center for Technology Innovation at Brookings. https://www.brookings.edu/wp-content/uploads/2016/06/West_Internet-Access.pdf

158 <https://economictimes.indiatimes.com/tech/internet/internet-users-in-india-to-reach-627-million-in-2019-report/articleshow/68288868.cms?from=mdr>

159 <https://www.cps.fgv.br/cps/telefonica/>

exhibits only 42.4% of residents having any sort of access to the internet, with only 1.6% having an active connection at home¹⁶⁰ (Figure 1.6.).

Figure 1.6. Percentage of households in South Africa with access to internet by province

Source: IOA (2017) based on the General Household Survey of Statistics South Africa, 2015¹⁶¹

The situation in Russia is overall more favorable and more even in terms of internet access. Even though the large territory makes it difficult to provide connection in the remote rural areas, and consequently some regions are worse off in terms of connectivity, the high rate of urbanization makes the issue of access a lesser concern overall.¹⁶²

1.2.3. Consumer-level effects

Digital competition is meant to bring consumers many benefits: lower prices, increased variety of available products and products better tailored to the consumer's specific needs, lower transaction costs, etc. However, a lack of competition in the digital sphere can lead to a redistribution of potential consumer gains towards the companies wielding high market power. Additionally, benefits from digitalization come with increased risks of identity theft, credit card or banking fraud, data collection by online services and a loss of control over personal data. Low trust in digital businesses on the consumer side can hinder further digital development, when consumers make significant changes to their behavior to avoid the risks associated with digital interactions – including making less payments and purchases via the internet.

The CIGI-IPSOS Global Survey on Internet Security and Trust (2019) shows that this is an acute issue for the BRICS countries, where consumers in the past year have made such

Source: Ipsos (2019)¹⁶³

As for the benefits that consumers can derive from digital competition, they are linked with the level of engagement with the digital economy that the consumers exhibit. The BRICS countries show considerable variation in this respect.

In terms of retail e-commerce sales, China is the indisputable leader – its market size in this dimension is larger than the aggregate of other BRICS countries (Figure 1.8.).

Figure 1.8.: BRICS e-commerce sales

Source: UNIDO, ITC (2017)¹⁶⁴, p. 19

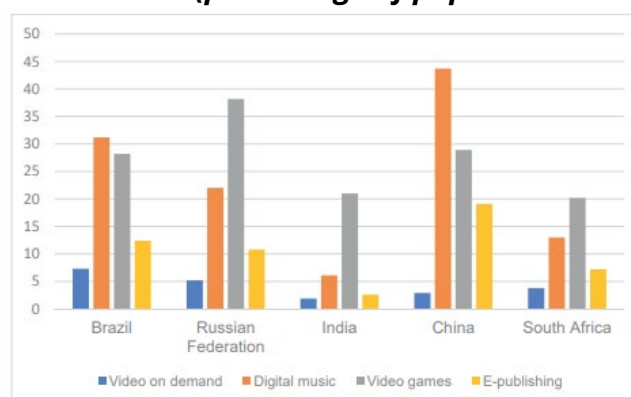

Although the size of China’s e-commerce market stems from a set of unique conditions impossible to match, it still shows that there is large potential for further e-commerce growth in other BRICS countries.

¹⁶³ 2019 CIGI-Ipsos Global Survey on Internet Security and Trust <https://www.cigionline.org/internet-survey-2019>

¹⁶⁴ UNIDO & ITC. Status, opportunity and challenges of BRICS e-commerce. 2 August 2017 [http://www.intracen.org/uploadedFiles/intracenorg/Content/Publications/BRICS%20E-commerce%20_Status%20Opportunities%20and%20Challenges_22AUG2017_final\(1\).pdf](http://www.intracen.org/uploadedFiles/intracenorg/Content/Publications/BRICS%20E-commerce%20_Status%20Opportunities%20and%20Challenges_22AUG2017_final(1).pdf)

Digital markets for specific categories of products also have varying popularity among consumers in the BRICS countries. Chinese and Brazilian consumers are actively engaging in the digital music segment, while Russian, Indian and South African consumers are relatively more engaged in the digital markets for video games (Figure 1.9.).

Figure 1.9. Digital market penetration rate, BRICS countries (percentage of population over 16)

Source: ITC (2017)¹⁶⁵

There is also area for further development concerning the engagement in online payment and buying products on the Internet (Figure 1.10.). Although the share of population that was paying bills and buying products on the Internet in 2014 was slightly higher than the world average in China and Russia, the other BRICS countries were behind the world average, with the most significant gap demonstrated by India.

Figure 1.10. Share of population that pays bills or buys things on the Internet, BRICS countries, 2014.

Source: ITC (2017)¹⁶⁶

Consequently, in most BRICS countries there is sufficient room for increasing consumer engagement with digital markets so they can share in the benefits provided by the digital economy. At the same time, developing countries are the ones that exhibit the most

165 International Trade Centre (2017). BRICS countries: Emerging players in global services trade. ITC, Geneva. http://www.intracen.org/uploadedFiles/intracenorg/Content/Publications/28_BRICS_Services_new_270717_final_Low-res.pdf

166 International Trade Centre (2017). BRICS countries: Emerging players in global services trade. ITC, Geneva. http://www.intracen.org/uploadedFiles/intracenorg/Content/Publications/28_BRICS_Services_new_270717_final_Low-res.pdf

caution and distrust towards digital interactions. This provides the reason why the governments of the BRICS countries need to specifically address the consumers' safety and privacy concerns so as not to impede the development of the digital sector.

1.3. The new global digital eco-system and BRICS: a political economy perspective on the relation between industrial policy and competition law and policy

1.3.1. Industrial policy and digital transformation: an overview

As the digitalization of markets continues, geographic market boundaries expand and gradually become less pronounced, allowing us to talk about global markets for digital services. Network effects, the decrease of transformation and transaction costs and a lowering of barriers to entry characteristic of digital technologies have a substantive part to play in the integration of digital markets, with efficient and innovative firms expanding their operations onto a global scale. Their expansion also brings about an increase of their market power, which poses a challenge for competition policy. On the one hand, hindering efficient expansion can stifle innovation and decrease consumer welfare in a dynamic setting. On the other hand, beside the general negative consequences of abuse of market power, the global aspect of digital markets entails at least two additional complications that make the competition problem not only a matter of efficient allocation of resources, but also a matter of distributive effects. If the dominant firms are based in higher income countries while their consumers are from developing countries, the market power abuse redistributes welfare from countries that are already at a technological disadvantage.

These effects could perhaps ultimately be mitigated by a consistent competition policy on affected markets, even if such a policy does not aim specifically at dealing with distributional impacts and focuses, following a more traditional view, on efficiency. But digitalization affects the economy not only on the level of isolated markets, but also along the global value chains in the digital sphere. The opening up of markets and the expanding of their geographical boundaries due to the spread of digital technologies can potentially induce an effect analogous to the Vanek-Reinert effect.¹⁶⁷

The idea behind the argument is that while developed countries have comparative advantages in increasing-return industries in global value chains, specialization leaves developing countries stuck with specializing in diminishing-return activities. The Vanek-Reinert effect demonstrates that a sudden transition to free trade can destroy the most efficient industries in a less efficient country and send it into a vicious circle of poverty. In the same vein, abruptly removing the barriers for global digital giants to function on domestic markets in a developing country can potentially have chilling effects for the country's own technological companies. Losing the battle to global players might mean cheaper and better services for the country's consumers in the short run. However, ulti-

167 Reinert E. (2007) How Rich Countries Got Rich... And why Poor Countries Stay Poor. Carrol & Graf, 365 p.

mately the country can become poorer and less technologically developed due to being forced out of the sectors with the most added value and characterized by the highest rates of innovation.

Striking an optimal balance between the stimulating effect of competition on efficiency and the need to enact some protecting measures for national markets and competitors requires a measured approach to industrial policy. While this approach would not completely renounce the benefits of global competition, it would provide enough support for certain national businesses to survive in the rapidly changing digital sector. In this sense industrial and competition policy do not necessarily come into conflict, but can rather be complementary. A horizontal industrial policy¹⁶⁸ can have a more favorable impact on competition than a vertical one: competition effects largely depend on the specific implemented instruments of industrial policy. Competition policy, in turn, can be guided not by a narrow definition of its goals and instruments, but by a more nuanced approach, recognizing the countries' relative positions along the global value chains and the possible distributive effects. Consequently, in this perspective, competition policy could be aligned with the goals of industrial policy and ensure a more holistic approach.

The need for a balanced approach to industrial and competition policy in the world of rapidly developing digital technologies calls for a political economy perspective on their interaction. This is especially important for BRICS countries, which, though sufficiently diverse, have much to gain from increasing digitalization in terms of overcoming internal challenges and enhancing their role in the global economy:

1) *Technological modernization*. Digitalization allows developing countries to skip a few technological stepping stones and proceed to implementing the most modern technologies. The case of China's rise of mobile payments is an example of this: Chinese consumers basically went straight from cash payments to mobile payments, skipping the stage of credit and debit cards.¹⁶⁹ In this regard, China took actions to delay the entry of foreign credit card companies in its territory, despite having clear commitments upon the accession to the World Trade Organization.¹⁷⁰

2) *Digital divide/digital inclusion*. As seen above, most BRICS countries are vast in size and characterized by significant regional economic and social differentiation. Internet access and the differing ability of consumers to navigate the digital sphere can increase regional inequality. Market forces are often not enough to stimulate

168 There are two ways to interpret vertical and horizontal industrial policy. On an inter-industry level, vertical policies focus on specific industries, while horizontal policies seek to improve operational conditions and capabilities across several sectors (UNCTAD, World Investment Report, 2018, p. 126). On an intra-industry level, vertical policy implies the support of specific enterprises, while horizontal policy allows support of enterprises if they are determined in accordance with objective criteria (Idrisov G., 2016. "Towards modern industrial policy for Russia," Research Paper Series, Gaidar Institute for Economic Policy, issue 169P)

169 See, e.g., Hill J. Fintech and the Remaking of Financial Institutions. Academ Press, 2018, p.277-278

170 Bernard Hoekman and Niall Meagher, 'China – Electronic Payment Services: Discrimination, Economic Development and the GATS' (2014) 13 World Trade Review 409, 441.

private companies to provide internet access in underdeveloped territories. Therefore, one of the goals of digital policy in developing countries can be ensuring universal internet access. Regional digital inequality can also contribute to the global digital divide which refers to the disparities of access to the internet and related services between higher income and middle and lower income countries.

3) *Access to technology.* Technological modernization demands access to technologies that can be concentrated in the hands of foreign companies. A typical problem is the amassing of technological patents by international companies that use them as a source of bargaining power against companies from developing countries. Therefore, the digital industrial policy needs to include provisions concerning possible ways of gaining access to such technologies – by substitution, acquisitions or other measures.

Having outlined the basic framework of our analysis and the main questions we hope to answer, it is now time to turn to the interplay of industrial and competition policy in the digital sphere in BRICS countries.

1.3.2. Framework of digital strategies

The BRICS countries have integrated digitalization into their strategic policies and have both used the already existing government strategic management tools and developed new ones specifically for the purposes of promoting digitalization.

In China the state plays a dominant role in shaping the digital economy. The current digital strategies and plans in China include the major “Made in China 2025” program as the overall planning strategy and number of more specific planning policies (Table 1.2.).

Table 1.2.. Digital economy strategies and plans in China

Overall planning policy	Specific planning policies
Made in China 2025	Action Outline for Promoting the Development of Big Data, Guiding Opinions on Vigorously Advancing the “Internet Plus” Action, and Guiding Opinions on Enhancing the Integrated Development of the Manufacturing Industry and the Internet

Source: (CACS, 2018, p. 124)¹⁷¹

“Made in China 2025” is a strategy enacted in 2015 and aimed at achieving the industrial modernization of the Chinese economy. The strategy corresponds to the “Industry 4.0” program of the German government. Its focus is promoting “smart manufacturing” technology as a means of upgrading industrial processes in order to boost the competitiveness of Chinese companies both on domestic and global markets. While in the short run this policy might provide attractive business opportunities for foreign firms, the policy’s end goal is to grow Chinese companies that are technologically advanced enough to compete in international markets in the sphere of cutting-edge technology.

171 Chinese Academy of Cyberspace Studies (2018) World Internet Development Report 2017. Springer. 312 p.

There are several government programs relevant to the digital economy in India. In 2015 the Government of India launched its “Digital India” campaign, aimed at building digital infrastructure and increasing the availability of Internet among citizens, especially living in poor regions, as well as promoting government services online, and supporting a number of industries. Domestic groups of interests that were affected by promoting the program include not only local IT firms supplying goods and services *for government programs of providing government services online*, but also digital firms gaining from the growing demand that stems from an increased population involvement in e-commerce¹⁷². One of the main targets of the “Digital India” campaign is improving digital literacy of the population and thus increasing involvement in digitalization and developing digital markets. A more widespread use of digital services in traditional industries is believed to improve the effectiveness of the Indian economy.

A more generalized policy that builds a framework around India’s targets in digital economy development and its place in global digital value chains along with ensuring digital sovereignty is the National Digital Communications Policy (2018). Taking into account the major role that India plays in software development, an important addition to the National Digital Communications Policy is the National Policy on Software Products (2019). The latest policy proposals include the Draft National e-Commerce Policy (2019), which addresses the provision of data sovereignty, as well as a large array of e-Commerce issues, including FDI rules, consumer protection and standardization; Draft e-Pharmacy Rules (2018) and Draft Digital Information Security in Healthcare Act (2017).

Brazil has also recently established its National Digital Transformation System centering around the Brazilian Digital Strategy (“EDB”, “E-Digital”). The strategy describes a system of 100 actions aimed at ensuring digital development. The main goals set in the strategy concern network infrastructure and broadening Internet access; research, development and innovation; trust in the use of ICT; education and professional training; international interaction; economical digital transformation (a data-based economy, a world of connected devices and new business models); citizenship and digital government, in articulation with the strategy of digital governance and the platform of digital citizenship¹⁷³. The governance structure of the Brazilian Digital Transformation Strategy was formally set up by Decree n 9.319, of 21 March 2018.

In Russia the framework strategic document in the digital sphere is the “Strategy for the Development of the Information Society in the Russian Federation for 2017-2030”, adopted in 2017. The strategy is supported by the State Programme on ‘Digital Economy of the Russian Federation’ (replaced by the Passport of the National Programme ‘Digital Economy of the Russian Federation’ in 2019). Much like in other BRICS countries, Russia’s digital strategy concerns the development of digital infrastructure, increasing the global competitiveness of Russian companies, creating new markets, decreasing entry

172 An example of promoting such initiatives is the innovation of Data Xgen Technologies Pvt Ltd that proposed the opportunity of creating email addresses in different languages named DataMail <https://www.datamail.in/aboutus.html>

173 Deloitte. Insights about Digital Transformation and ICT Opportunities for Brazil Report and Recommendations. January 2019, edition No 2 <https://www2.deloitte.com/content/dam/Deloitte/br/Documents/technology-media-telecommunications/ICT-insights-report-eng.pdf>

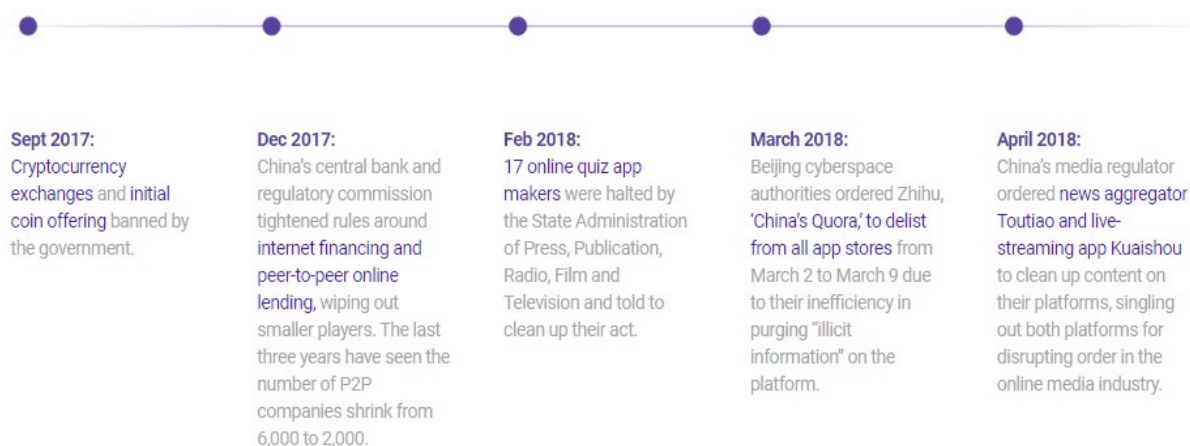

barriers in the digital sphere and treating data as a valuable resource. A feature that perhaps distinguishes Russia's strategy is the explicitly stated role of competition policy and its need to be updated to better correspond to the issues of the digital economy. This point serves to underscore the comparatively more active role that the Russian competition authority plays in digital industrial policy, which will be touched upon later.

1.3.3. Degree of prudence in introducing regulation

The BRICS countries mostly strive to adhere to a measured approach to regulating the digital sphere, taking care not to stifle new and emerging markets and technologies with over-regulation. When serious issues do arise, the goal is to react swiftly to avoid large losses in terms of consumer welfare and security. So far most of the regulations have had to do with security concerns, mainly concerning data storage and access, as well as cybersecurity.

Concerning specific regulation, China has promoted a "tolerant and prudent" approach to regulating the digital sphere, being careful not to stifle innovation with excessive regulatory reaction to emerging technologies and business practices. That is not to say that the state has been inactive in digital regulation, prompting the authors of the "China Internet Report 2018" to name the government "The Visible Hand" in China's digital development¹⁷⁴. As can be seen from Figure 1.11, the prohibitive regulations imposed in 2017-2018 have mostly been based on security concerns.

Figure 1.11. Chinese regulation measures in the digital sphere in 2017-2018

Source: <https://www.abacusnews.com/china-internet-report/>

In this stance, China is accompanied by India, which is also choosing a cautious approach to regulation in the digital sphere, avoiding excessive regulatory intervention. The position is also shared by the competition authority. Most of the specific regulations and policies are either recently enacted or currently being drafted and discussed, while the digital sector mostly operates under the already established general framework of rules

174 South China Morning Post (2019). China Internet Report 2019. China Internet Report. [online] South China Morning Post Publishers Ltd. Available at: <https://www.abacusnews.com/china-internet-report> [Accessed 1 Aug. 2019].

and regulations. The specific issues that have been identified in India's digital economy – now being addressed through regulation – are issues of personal data security (Draft Personal Data Protection Bill, 2018), FDI in e-Commerce (Press Note 2 of 2018 clarifying The Consolidated FDI Policy, 2017) and payment data localization (RBI Notification on Storage of Payment System Data, 2018). Yet, as has been shown above, a prudent regulatory approach does not mean a lack of industrial policy in the digital sphere.

Russia has enacted an array of security-centered laws that entail a significant increase of costs for ICT firms (and therefore have been met with criticism). These include laws known as the 'Yarovaya package' and Russia's Sovereign Internet Law. The 'Yarovaya package', among other things, concerns the mandatory storage of citizens' digital communication data and providing the authorities access to encrypted data from messaging services, emails and social networks. Russia's Sovereign Internet Law that will take effect in November 2019 is meant to ensure the safe and sustainable functioning of the Russian segment of the internet, but it imposes large additional costs on the internet providers, i.e. by obliging them to install devices to filter traffic. Those laws apply to ICT and digital companies that function in Russia but that does not ensure that the competitive effects will be fairly distributed. For example, national companies whose main business is in Russia, but which also compete internationally, will be burdened with significant additional costs of complying with new regulation – costs that may very well undermine their international competitiveness.

In Brazil, regulators have taken a cautious stance regarding issues in digital markets. Regulations affecting digital platforms are enacted by different regulatory authorities, responsible for telecommunications, data protection, consumer protection, e-government, and intellectual property among others. The sectoral regulators are generally well placed and equipped to deal with the digital aspects of their sectors, but they have been careful not to overstep their powers. They have generally avoided undue intervention in very dynamic markets. This has not deterred the authority from intervening in certain competition cases, as reported in Brazil's media.

1.3.4. Providing internet access

The backbone of digital development is access to the internet for businesses and citizens. The BRICS countries have each developed measures to ensure increasing coverage through broadband and mobile internet. In Russia, the Federal Law 'On Communication' places additional obligations to provide internet access in settlements with small population sizes onto operators that occupy a significant position in the public communication network on the territories of not less than 2/3 of the regions of the Russian Federation. Currently the only company that qualifies for the status is the state-owned company Rostelecom. China is implementing a special "Broadband China" strategy that aims to significantly increase the levels of fixed broadband and 3G/ Long-Term Evolution (LTE) access as well as to ensure higher speed of access. In India the National Digital Communications Policy 2018 set one of its goals to be universal digital access in 2022. Brazil has

been using General Plans of Universalization Goals (in Portuguese, *Plano Geral de Metas de Universalização* or “PGMU”) to set universal access targets for telecom companies that have emerged after the privatization of the previously state-owned telecom giant Telebrás in 1998. The current plan is focused on expanding backhaul infrastructure and mobile Long-Term Evolution (LTE) in small cities, to make broadband access available to all; a major challenge in a country of continental dimensions and deep inequality.

The states’ efforts are often backed by forces of competition between mobile operators.

Figure 1.12 . Percentage of individuals using the internet in BRICS (U.S. and France included for reference) in 2017

Source: ITU

One of the problems that remains acute for BRICS countries is, as mentioned earlier, the digital divide between a country’s regions, specifically between rural and urban areas. Consequently, decreasing the divide remains a policy target for each BRICS country.

Internet and mobile penetration rates are only one side of the coin when it comes to accessibility. The other side is affordability – and here the BRICS countries are demonstrating a positive dynamic, offering affordability on a level similar and even exceeding some of the higher income countries.

One way to capture these aspects is the Inclusive Internet Index that measures for categories: availability, affordability, readiness (literacy, trust and safety, policy) and relevance (local content, relevant content).¹⁷⁵ Table 1.3. shows where each BRICS ranked by the Inclusive Internet Index in 2017.

175 The Economist Intelligence Unit Limited (2017). The Inclusive Internet Index: Bridging digital divides. The Inclusive Internet Index. [online] The Economist Intelligence Unit Limited. Available at: <https://theinclusiveinternet.eiu.com/assets/external/downloads/3i-bridging-digital-divides.pdf> [Accessed 1 Apr. 2019].

Brazil	18
South Africa	27
China	29
India	36

Source: <https://theinclusiveinternet.eiu.com/assets/external/downloads/3i-bridging-digital-divides.pdf>

In some of the BRICS countries competition authorities have contributed to making internet access and mobile telephony more affordable. In Russia the Federal Antimonopoly Service has led a series of cases against mobile operators dealing with excessive prices for intra-network and national roaming which have later been supported by industry regulation banning both types of excess roaming charges.¹⁷⁶ In China competition authorities have also conducted several investigations against its three network operators (China Mobile, China Telecom, China Unicom) which ended up suspended due to the companies making commitments to improve their conduct in line with the requirements of antitrust law, as reported in China's media. In Brazil, there has been some significant competition enforcement in infrastructure access, especially in telecommunications markets that give support to internet services. Merger control and settlements were used to tackle the access to infrastructure and to public utilities owned by former incumbents, as highlighted in the Brazilian press.

1.3.5. Data sovereignty

All the BRICS countries have demonstrated awareness of the specific problems that customers face when participating in digital markets and have implemented regulation changes in order to better reflect these new challenges, in particular concerning data and privacy protection. What, in a sense, sets the BRICS countries apart from the more developed countries is the particular challenges the former face in terms of data protection and the subsequent goals that are to be achieved in this field.

One such challenge is the provision of 'digital sovereignty', a definitive part of which is data sovereignty. The term has not been defined either in literature, or across formal country policies, but in a general sense it can be viewed to mean an "attempt by nation states to subject data flows to national jurisdictions".¹⁷⁷ Though the concern is communal for BRICS countries, Polatin-Reuben and Wright (2015) point out the difference in approaches: while China and Russia are considered by them to lean towards "strong data sovereignty" ("a state-led approach with an emphasis on safeguarding national

176 En.fas.gov.ru. (2019). ABOLISHING ROAMING IN RUSSIA IS RECOGNIZED THE BEST FAS CASE | Федеральная Антимонопольная Служба - ФАС России. [online] Available at: <http://en.fas.gov.ru/press-center/news/detail.html?id=54111> [Accessed 1 Aug. 2019].

177 Polatin-Reuben, Dana, and Joss Wright. 2014. "An Internet with BRICS Characteristics: Data Sovereignty and the Balkanisation of the Internet," July. <https://www.usenix.org/system/files/conference/foci14/foci14-polatin-reuben.pdf>

security”¹⁷⁸), India and South Africa choose the “weak data sovereignty” (“private sector-led data protection initiatives with an emphasis on the digital-rights aspects of data sovereignty”¹⁷⁹) approach, with Brazil’s position being more centered between these poles. But the increasing relevance of the challenges of data protection has led to a shift of approaches: since the work of Polatin-Reuben and Wright was published in 2015, India is currently in the process of developing digital sovereignty and data localization regulations, along with establishing preferences for local companies in acquiring access to data, which would move it into the “strong data sovereignty” category.

The possible effects for competition of data sovereignty (including data localization) regulations depends on the specific forms. Generally speaking, these measures are seen by affected parties and countries as protectionist¹⁸⁰ and hindering global competition.¹⁸¹ They might be viewed as a type of industrial policy. If these regulations are complemented by provisions of preferential access to data for local companies, as proposed by the draft regulation in India, then these regulations can contribute to leveling the playing field with global companies. BRICS national markets are large enough to provide significant competitive advantages through processing their data.

As for competition authorities, their approach to the need to incorporate privacy, data protection and data access effects in their analysis is not uniform. Brazil’s competition authority has repeatedly concluded that data and privacy concerns do not come under its authority. On this matter, the Brazilian Administrative Council for Economic Defense (CADE) acknowledged the importance of the data and privacy discussions, but confirmed that the evaluation of privacy concerns should be carried out by authorities such as the Department of Consumer Protection, the telecommunications regulator, and the Internet Management Committee.¹⁸² On the other hand, the Russian competition regulator has attempted to include into competition law provisions concerning access to data.¹⁸³

1.3.6. Protectionist aspects of digital policy

As pointed out earlier in discussion of the Vanek-Reinert effects, although typically barrier reduction and easier market penetration are associated with more vigorous competition, such unbounded competition may be detrimental to local businesses. In terms of market concentration, this may lead to more concentrated markets after international corporations take over domestic markets. The outcome is especially detrimental to the less developed countries’ digital sphere, which, as seen before, is globally dominated by

firms from more developed countries. This leaves the less developed countries' domestic production to concentrate on industries that yield a significantly lesser amount of value in the global value chains, thus furthering inequality between countries.

Some of the BRICS countries see their strategies for the support of their digital transformation as an opportunity to lessen their dependence on imports of technology. This intent is clear, for example, in the regulations introduced and currently being proposed in the Russian software markets. For example, in 2015, public authorities became obligated to only purchase Russian software¹⁸⁴. Exceptions can be made only in those cases when foreign software does not have Russian substitutes or when those substitutes do not fulfill the buyer's requirements¹⁸⁵. Later on, software from the Eurasian Economic Union was also admitted into the procurement process. Additionally, one of the latest government initiatives (not yet in force) is the requirement to pre-install Russian apps on smartphones that are sold in the country.

As for China's "Made in China 2025" strategy, Wübbecke et al. (2016)¹⁸⁶ argue that, judging by the wording of the strategy, it aims at gradually replacing foreign technology with Chinese technology. The strategy is not only domestic: the goal is also to prepare the ground for Chinese technology companies entering international markets. According to the report, the strategy intends to increase the domestic market share of Chinese suppliers for "basic core components and important basic materials" to 70 per cent by the year 2025. Semi-official documents related to the strategy set very concrete benchmarks for certain segments: 40 per cent of mobile phone chips on the Chinese market are supposed to be produced in China by 2025, as well as 70 per cent of industrial robots and 80 per cent of renewable energy equipment.¹⁸⁷ These targets confirm the import substitution trend.

A number of barriers either naturally exist or are maintained that carve out a market for Chinese firms to improve and develop, to the point where some of them become globally competitive. Firstly, there is the language barrier, but other barriers are put in place mostly through government policy. The combination of regulations known as "The Great Firewall of China", for example, by limiting access to foreign websites, search engines and apps, has channeled the existing demand for these services into Chinese analogues.

India's regulatory framework allows for differing regulations concerning foreign and local digital companies, especially in sectors where there are restrictions on the share of FDI allowed to take place. The proposed restrictions that accompany the digital sover-

185 In practice many buyers circumvent this restriction, either because Russian substitutes for the software in fact do not exist, or by formulating requirements in such a way that the substitutes do not fulfill them.

187 Ibid, p. 7

eighty policy and concern access to Indian data for foreign firms are also a measure that can provide support to local digital players.

1.3.7. Role of the competition authority

In the majority of BRICS countries, the competition authority's main focus concerning digital industrial policy is twofold. The first major function is careful antitrust enforcement based on the understanding of the specific features of digital businesses and the associated factors of risks and benefits. In this way, the competition authority ensures that competition in the digital sector remains fair and that the losses of consumer welfare do not outweigh the benefits of the digital economy. The second major function is the assessment of the competitive effects of policies and regulations introduced in the digital sphere.

Brazil's competition authority demonstrates a focus on competition effects and a commitment to the traditional goals of antitrust policy, ensuring that these are not forgotten among discussions of other issues pertaining to digital markets. Existing competition law is successfully applied to digital platforms and markets, and CADE and the Secretariat for Competition Advocacy and Competitiveness of the Ministry of Economy ("SACC", in the Portuguese acronym) additionally undertake efforts to advocate and promote competition in the digital sector. Although SACC takes the primary role of competition advocacy, championing pro-competition regulatory actions within the government, CADE may also have specific advocacy initiatives.

India's current enforcement of competition law in the digital sector has so far presumed the possibility to adapt the already existing law to the particular issues of digital markets. As noted earlier, India exhibits a rather prudent approach to both regulation and competition law enforcement in the digital sphere. In 2018-2019 the Government of India has been taking steps to begin a review of competition law, which might result in the competition authority acquiring new instruments for dealing with violations in digital markets.

India's competition authority also has the power to provide expertise concerning possible anticompetitive effects of decisions made by sectoral regulators upon request. However, the authority's opinion is not binding for the regulator, the competition authority's influence being limited.

In recent years China has established a fair competition review system encompassing policies enacted at the central and local government levels, which ensures that digital policies that pose significant competition risks will not be implemented. The competition authority can make suggestions and offer opinions during the policy-making stage. Additionally, the authority has powers to address the abuse of administrative power – in case a policy is enacted and leads to a restriction of competition – by proposing higher authorities to deal with the authority that enacted the policy under concern. As for competition law enforcement, the authority tries to avoid overenforcement, guided by the understanding that digital markets are still emerging. Nevertheless, a draft addition to

the competition law (“Provisions on the Prohibition of Abuse of Market Dominant Status (Draft for Comment)”) demonstrates a recent shift towards explicitly recognizing the role of data as a source of dominance in digital markets.¹⁸⁸

The Russian competition authority, in its turn, appears to be playing a much larger role in digital industrial policy than its colleague in other BRICS countries. Aside from ensuring antitrust enforcement in digital markets, the Russian competition authority has proposed to introduce major changes to competition law that are meant to better reflect the specific traits of the digital economy, including platform markets, the role of Big Data and network effects. The cases investigated by the Federal Antimonopoly Service of Russia (FAS) have also become the basis for and aligned with the regulation that was subsequently introduced or has been proposed in the digital sector. Examples include the authority's decisions on intra-network and national roaming charges by mobile operators that were later abolished by sector regulation, as well as the current proposal to introduce obligations of pre-installment of Russian apps on smartphones sold in Russia – based on the case of *Yandex v. Google*.¹⁸⁹

The digital strategies introduced in the BRICS countries in a sense influence competition law enforcement. These strategies underscore the importance of the digital sector for modern development, which ensures that special attention is paid to all the antitrust investigations and merger reviews concerning digital markets. Moreover, there is an increased awareness that these cases pose distinct challenges for competition law enforcement stemming from the particular characteristics of digital businesses and markets. Therefore, authorities view these cases as relatively complex and give them even more attention.

1.3.8. Mergers

Concerning merger review, competition law enforcement in the BRICS countries seems to recognize the specific efficiencies in digital markets that accompany the increase of market share. For example, despite some interventions, Brazil's competition authority has cleared the vast majority of mergers in the digital economy without restrictions. The decisions which involved restrictions ranged from the exclusion of non-competition clauses to the assumption of behavioural and structural commitments, some of them related to the provision of internet connectivity. Russia's competition authority, as well, has recently analyzed – and approved – a major deal between Uber and Russia's Yandex.Taxi concerning the consolidation of their online taxi hailing business in Russia and neighboring states.

The amassing of patents in the hands of global firms is a widespread challenge for different industries in developing countries. The merger approval process is one of the ways to alleviate this problem and to provide general access to technologies or access on better conditions. To illustrate, in Brazil, the transfer of IP rights is among the struc-

188 See files on China's media.

189 See files on Russia's media.

tural remedies that can be imposed by CADE or agreed by the parties to a notified transaction and compulsory licensing of IP rights is one of the measures that can be imposed to approve a merger.¹⁹⁰

A practical example is the recent Bayer-Monsanto merger, which was reviewed, analyzed and approved by all the BRICS competition authorities. Some of the decisions on this merger included provisions of access to technologies. For instance, China's MOFCOM, aside from structural conditions on the divestiture of parts of Bayer-Monsanto's global business, required the merged firm to provide access to its digital agricultural platform for Chinese agricultural software and application developers (and to allow Chinese users to register and use the products or application programs of digital agriculture). Such measures have the potential to promote the dissemination of technologies, strengthen the bargaining power of the merged firm's counterparts on different sides of the market and promote competition in adjacent markets.

A complementary issue is the reflection of BRICS's digital strategies in foreign merger policies. Apart from acquiring access to technologies through merger approval conditions, as in the Bayer-Monsanto case, another way of gaining access, as mentioned, is acquiring foreign technological companies. Here Chinese companies have had varying success. The largest deal so far has been the acquisition of the Swiss Syngenta company by ChemChina, a deal prompted by China's desire to use Syngenta's portfolio of top-tier chemicals and patent-protected seeds to improve domestic agricultural output¹⁹¹.

Other deals – concerning, for instance, US companies – have been blocked by various reasons, mainly through the invocation of legislation concerning foreign investment. The examples include the attempts of Ant Financial (sister company of the Alibaba Group) to buy the US money-transfer provider MoneyGram, of a Chinese-funded private equity firm to purchase Lattice Semiconductor, an American chip manufacturer and of another proposed deal by a Chinese fund to buy Xcerra (a provider of equipment for testing computer chips and circuit boards).¹⁹² As will be developed in Section 1.8.1, the trade wars exacerbate the fears of foreign investments for strategic acquisitions.

1.3.9. Investigations of competition law violations

The countries' digital strategies seem to also have an impact on the cases investigated by the competition authorities. Mainly this is reflected in the types of conduct that draw inquiries from the competition authorities – especially in cases dealing with foreign firms. If these cases end up being decided in favor of local companies, this might evidence certain protectionist aims. However, overall the outcomes of the cases vary and are not always in favor of the domestic firms.

190 See Law 12,529, of 30 November 2011, art. 61, §2, V.

191 Fortune. (2017). ChemChina Clinches Its \$43 Billion Takeover of Syngenta. [online] Available at: <http://fortune.com/2017/05/05/chemchina-syngenta-deal-acquisition/> [Accessed 1 Apr. 2019].

192 New York Times. (2018). China Microchips. [online] Available at: <https://www.nytimes.com/2018/02/23/technology/china-microchips-c-us-xcerra.html> [Accessed 1 Apr. 2019].

An example of conduct that draws scrutiny from competition authorities in BRICS is dominant foreign companies using data gathered from local consumers to further increase their market power and earnings. In the case *Shri Vinod Kumar Gupta against WhatsApp Inc.* in India the alleged abusive conduct of WhatsApp consisted of sharing users' private information with Facebook (which has owned WhatsApp since 2014), which in turn was being used by Facebook for targeted advertisements, as well as predatory pricing – by providing free services since 2016. The CCI, after considering the case, did not find a violation. However, the case emphasizes how the importance of data in the digital economy in conjunction with private information protection issues coincide with the low rate of digital literacy in India. The case with WhatsApp demonstrates that the privacy policy implemented by one firm can affect the market share of another firm in the same group. Thus one digital product supplied for free can be the source of data for another product which can be monetized (for example) through advertising. It follows that privacy policies and the level of digital literacy can affect data distribution and allocation efficiency in different markets.

A case that addresses the opportunity of platforms to gain market share using network effects and the interaction of international firms with local competitors is the *Meru Travel Solutions Pvt. Ltd. against Ola and Uber* case in India. The alleged anticompetitive conduct of Ola and Uber related to the incentive model of providing unrealistic incentives to the drivers and discounts to customers in addition to low fares. According to the claim, this was aimed at gaining a high market share and foreclosing competition in the market by creating entry barriers through anticompetitive agreement between Uber/Ola and its driver-partners. The CCI again found no violation, indicating that drivers and riders can easily switch from using one aggregator to another, thus there is no entry barriers and no dominant position of any one aggregator.

Although both cases were resolved in favor of the foreign digital companies (with the exception of Ola, which is one of the biggest Indian online transportation network companies), they indicate a sense of unfairness expressed by the plaintiffs and the perception that local firms and consumers should be protected against the bargaining power of global digital players.

An adjacent issue is not simply protection, but active support of local companies as global players. China's Qualcomm case illustrates the challenge of achieving strategic goals in the digital sphere and promoting innovation while being dependent on foreign technology. In 2015 China fined Qualcomm more than 6 bn yuan for abusing its dominant position and charging unfairly high licensing fees, improperly bundling unrelated licenses and including "no-challenge" clauses in its licensing agreements¹⁹³. The case highlights the key problem with access to technology and its distributional effects. Chi-

na's position as a hub for manufacturing devices for internet access makes it dependent on certain high-tech components supplied by global companies. As these companies hold the bulk of patents for these technologies, substitution is unlikely. This opens up opportunities for global companies to exploit their market power and redistribute value from Chinese companies. Competition policy, by imposing constraints on the types of behavior such a dominant firm can engage in, can serve to improve the conditions of access to important technologies and redistribute in return some of the value that was originally absorbed by the global companies.

Russia's biggest cases in the digital and tech spheres – Yandex v. Google and Kaspersky Laboratory v. Microsoft¹⁹⁴ – have also been resolved in favor of domestic companies that also compete on international markets (Yandex and Kaspersky Laboratory respectively). This does not necessarily indicate a protectionist bias, but it is important to note that the FAS has previously been criticized for appearing to underenforce the law when large foreign firms are concerned and over-enforce it to the detriment of smaller domestic companies¹⁹⁵. In any case – whether it was intentional or not – the decisions in favor of Yandex and Kaspersky Lab help mitigate this criticism. However, the protectionist *effect* of at least one of these decisions – the Yandex v. Google one – has been further enhanced by FAS's policy proposal to require the pre-installment of Russian apps on smartphones.

As for the issue of underenforcement or overenforcement in the case of platforms, competition authorities in the BRICS countries have proven that they are not afraid to take on cases of digital platforms. Good illustrations are the WhatsApp and Ola/Uber cases in India, mentioned above along with the CCI case against Google on issues of search and advertising; the Google and Microsoft cases in Russia; the Renren v. Baidu case in China and cases concerning Tencent's messaging platform WeChat; and the Brazilian cases against hotel booking platforms and credit card companies. Some of these cases like the Google cases in India and Russia correspond to cases brought against Google by the EU. Taking into account some of the methodological difficulties associated with bringing cases against digital platforms, it is unwise to assume an overenforcement trend.

A recent trend in public discussion centers around data showing an increase of economic concentration in some of the major economies in recent years. For the U.S., Shapiro (2018) presents a thorough summary of the data, press articles and policy papers describing the growth of economic concentration during the past two decades, as well as a critique of the data and some of its interpretations.¹⁹⁶ Generally speaking, the main issue to discuss concerning the links between the apparent increase in global market concentration and the need for a more vigorous competition policy is whether the in-

196 Shapiro, Carl (2018) Antitrust in a time of populism, *International Journal of Industrial Organization*, Volume 61, 2018, P. 714-748, [accessed on 01.03.2019] <https://doi.org/10.1016/j.ijindorg.2018.01.001>. <https://www.sciencedirect.com/science/article/pii/S0167718718300031?via%3Dihub#keys0002>

crease in industry concentration (if it really exists) signifies an increase in market power.

There are two main suggestions on the limitation of industry concentration data. First, that industry concentration is too aggregated a measure for competition analysis that usually deals with market concentration, and there is no method reliable enough to infer market concentration from industry-level data. Second, that even market level concentration is an imperfect indicator of market power, and perhaps we should be using alternative measures if we want to find out whether there in fact was an increase in market power of firms in the last two decades. Finally, the rise in levels of concentration is frequently being associated with the digital sector, with its large economies of scale and scope enhanced by network effects that logically lead to high levels of market concentration and the emergence of “superstar firms”. As the digital sector gains importance and weight in the economy, its high concentration can affect the overall level. It follows that another issue to be analyzed is whether the digital sector is the main contributor to the growth of aggregate concentration levels.

In the literature, an increase in industry-level concentration in the U.S. has been confirmed in Furman & Orszag (2015),¹⁹⁷ – who also note some upward trends in profits in earnings inequality, Autor et al. (2017)¹⁹⁸, Bessen (2017)¹⁹⁹, Gutierrez & Philippon (2016, 2017)²⁰⁰, Döttling et al. (2017)²⁰¹, Grullon et al. (2018)²⁰². The latter also find that the industries with the largest increases in concentration are characterized by higher profit margins and more profitable M&A deals, while the overall increase in concentration found in the study is not accompanied by a significant operational efficiency difference. This in sum suggests that market power is becoming an important source of value. Increased mark-ups in the U.S. are also demonstrated in De Loecker, & Eeckhout (2017)²⁰³, who also find that the increase is due to a sharp increase in high mark-up firms. Gutierrez & Philippon (2016, 2017) find that increased market concentration is accompanied by reduced capital investment. Barkai (2017)²⁰⁴ shows that increased concentration trends are connected with a sharp rise in excess profits (capital return above the level

required to attract investors). All of these studies seem to indicate that market power, measured from different angles, is rising. Still, the level of aggregation remains a point of critique. In this vein, Rossi-Hansberg et al. (2018)²⁰⁵ find that national concentration trends, when disaggregated to the local level, become a pattern of de-concentration in a number of industries.

Among studies dealing with estimates for market power dynamics in other countries, Bajgar et al. (2019)²⁰⁶ take a look at 10 industries both in Europe and in North America from 2000 to 2014 and demonstrate an increase of the level of concentration (measured as the share of the 10 largest companies in an industry). By contrast, Döttling et al. (2017) are able to confirm an increase in the U.S., but a decrease in Europe, using HHI for measuring concentration).

Concerning industry mark-ups as a possible measure of market power, Andrews et al., 2018²⁰⁷, show industry data in a sample of 22 OECD countries revealing an upward trend in industry mark-up level. In Calligaris et al., 2018²⁰⁸, firm-level data in a sample of 26 countries (including, out of the BRICS countries, India) is studied in the period from 2001 to 2014, and the upward trend in mark-up level, on average across country, is confirmed. Pertaining to the analysis of BRICS countries, the most interesting is the study by De Loecker and Eeckhout (2018)²⁰⁹, who extract data from the financial statements of over 70,000 firms in 134 countries, including the BRICS. They show that in the last four decades the average global mark-up has increased from 1.1% to 1.6% (Figure 1.13.).

As can be seen from Figure 1.13 the highest mark-up among the BRICS countries is exhibited by Russia (higher than 1.16). Brazil falls in the category of 1.5-1.75 mark-ups. China, India and South Africa exhibit average mark-ups in the lower range of 1.25-1.5.

The increase in mark-ups in 1980-2016 is distributed unevenly across regions: mark-ups have risen the most in North America and Europe, and the least in emerging countries in Latin America and Asia (Figure 1.14.).

Figure 1.14. Changes in mark-up, 1980-2016

Source: (De Loecker, Eeckhout, 2018, p. 13).

Here Russia stands out among other BRICS countries with an exceptionally high markup growth, but taking into account the period of measurement, the time coincides with the transformation from a planned economy to a market economy. Thus the substantial mark-up increase should not be too surprising.

As for the role of the digital sector in the rise of concentration levels, the evidence appears to be inconclusive. Bessen (2017) finds a general link between levels of concentration and the use of information technology. Mandel (2018)²¹⁰ points out that in the results of Autor et al. (2017) most of the rise in concentration in services happened in the 1990s and early 2000s, when the “superstar” digital companies such as Facebook, Google and Amazon either did not exist or were very small in size. Bajgar et al. (2019), studying 10 industries in Europe and in North America, have demonstrated, as mentioned, an increase in the level of concentration, but at the same have found no significant difference in the dynamics of the digital-intensive sectors. Calligaris et al. (2018), by contrast, have found that mark-ups are higher in digital-intensive sectors than in less-digitally intensive sectors, and that mark-up differentials between digitally-intensive and less-digitally intensive sectors also have increased significantly over time.

In conclusion, the rise of industry concentration and mark-ups appears to be a trend in most of the world. However, as this rise is observed on a highly aggregated level – that is at a level above the product and geographical boundaries of actual markets – it does not

210 Mandel M. Competition and Concentration: How the Tech/Telecom/ Ecommerce Sector is Outperforming the Rest of the Private Sector. Progressive Policy Institute, November 2018 <https://www.progressivepolicy.org/publications/competition-and-concentration-how-the-tech-telecom-ecommerce-sector-is-outperforming-the-rest-of-the-private-sector/>

strictly prove a rise in market power. Even if we do merge these phenomena together and consider industry concentration and mark-ups to approximate market power, the upward trend seems to be less pronounced in less developed countries, particularly in BRICS. As for the high concentration of digital markets, its role in the overall trend remains inconclusive, although it is hard to deny the “natural” tendency of digital markets to become concentrated.

1.4. Digital trade and markets: an international governance perspective

1.4.1. General context of digital trade

The World Trade Organisation (WTO) has long recognized that global digital trade²¹¹ is growing and creating new opportunities,²¹² and established a work programme on e-commerce.²¹³ It defined e-commerce as “the production, distribution, marketing, sale or delivery of goods and services by electronic means.”²¹⁴ At the end of 2017, ministers of trade of WTO member states discussed whether the WTO should start negotiations on digital trade. The members were unable to consolidate the several proposals on digital trade, including a call for the creation of a central forum on e-commerce negotiations. Although a group of 70 WTO members decided to start the work on consolidated e-commerce rules,²¹⁵ it is clear that consensus is far away.

That same year the BRICS countries signed the E-commerce Cooperation Initiative²¹⁶ and established the E-Commerce Working Group. The United Nations Industrial Development Organization (UNIDO) and the International Trade Centre (ITC) analysed the BRICS e-commerce ecosystem. Apart from challenges unique to each country, they identified a number of challenges common to all BRICS countries, including “bureaucratic procedures, unfavorable tax regimes, underdeveloped delivery infrastructure, a lack of e-commerce skills in SMEs, hindering their ability to compete with larger companies, and adequate mechanisms for ensuring privacy and security of data.”²¹⁷

In this regard, several tendencies in the changing global trade landscape can be outlined. First, digital trade does not simply mean automation of processes and stages typical for traditional trade. The very centers of value creation are changing, and new market mod-

211 Digital trade and e-commerce are used interchangeably for the purposes of this chapter.

els emerge (e.g. the sharing economy, crowdsourcing). Further, the product life cycle in the digital environment involves storage, transfer and tracing of its digital twin – a virtual representation thereof reflecting the key characteristics of a real object. This means that e-commerce may involve trade in digital twins rather than the goods themselves. Beyond that, a pertinent regulatory problem is the fading boundary between goods and services and ensuing uncertainty in application of trade rules, as will be seen. The share of services in the production processes has increased. This includes engineering, design, research and other services which are often coordinated electronically. Thus, services are becoming an integral part of “smart goods” and the incorporated technology is increasingly protected by intellectual property rights. Companies are changing the focus of their main activities, removing boundaries between traditional sectors.

Second, as new roles and market participants emerge, one can notice the replacement of a number of players and the transformation of the intermediary layer. Producers begin to engage with consumers directly. This leads to an internal transformation of companies: they change their internal structures, reorganize their storage systems, decision-making systems, and channels of communication. Companies that manage to form their own ecosystems become more competitive. Thus, considerable market share of transportation, digital trade, and payments are now occupied by companies initially formed in the IT sector (e.g. Google or Yandex). Retailers that use digital trade channels start developing and implementing accompanying services, such as warehouse management, logistical networks, e-payments, and lending and insurance services.

Third, markets are dominated by global ecosystems (such as Alibaba or Amazon) as they ensure effective processes and fast interaction with partners, which is not available for small and isolated companies. Global ecosystems expand geographically claiming new sectors and market segments and attracting new participants both on the consumer and producer sides. This definitely brings challenges to digital trade governance.

Fourth, consumers are becoming active participants of digital trade. Trade platforms often do not own the goods they trade. The loyalty of their customers becomes their main asset. Trying to improve consumer experience, digital platforms and producers selling via internet propose new services, striving to accelerate supply chains and to create new trade channels. This is a two-way street that jointly creates value with platform participants. Approaches to building relations between producers and consumers are also undergoing profound changes, bringing data transfers to the forefront as consumers become co-producers and co-designers. They actively participate with their data, as well creating the content independently in the form of reviews, comments and complaints. The consumer also becomes a “seller” by providing data about his or her preferences and models of behaviour. Such data open massive opportunities for forecasting, and the improvement of consumer properties of goods, managing inventory, etc., turning them into selling assets that ensure the competitiveness of market participants. In the end, consumers and digital platforms determine what relationship models are to be formed in the digital environment. This requires international trade rules that encompass the new reality.

Such internet presence leaves a digital footprint, which includes browsing and shopping history, goods ratings, inquiries, opinions, emotions and the influence of community leaders. This data can serve as an invaluable asset for companies. Data analysis allows the creation of more attractive recommendations for consumers and the formation of targeted marketing strategies. Companies also use data to adjust production plans, reduce warehouse costs, and increasing business effectiveness. Development of successful models of data monetization becomes a vital issue for companies of all sectors.

1.4.2. Inter-jurisdictional data transfers: an overview

Given these developments, data is becoming the main resource and source of capitalization in digital trade. According to the World Bank, “firms need a free flow of data to operate across national borders, especially as production processes become more fragmented and goods and services become more digitized.”²¹⁸ Between 2005 and 2014 the volume of cross-border data flows has increased 45 times and added USD 2.8 trillion to world GDP, surpassing global trade in goods.²¹⁹ The explosive growth is ongoing.²²⁰ As argued in the note by the UNCTAD Secretariat:

Digital data are becoming an essential input in decision-making, production processes, transactions and relationship management across an ever-increasing swath of the agricultural, manufacturing and services sectors. As the digital economy evolves further, data will become even more inextricably interwoven with all aspects of the world economy, including the functioning of the Internet, global value chains and international trade.²²¹

The provision of communication, health, education, retail, tourism, entertainment or financial services on an international basis naturally leads to cross-border data flows. The increase in the role of data and data flows has been reflected in the servicification²²² of production allowing producers to increase added value and create sustainable relations with consumers. Therefore, there is a close linkage between international trade in services – in the form of the digital provision of international services – and the collection of data.²²³

Not all cross-border data flows bring direct information about trade. Data flows can provide information on markets or can coordinate production processes. However, barriers which hinder cross-border data flows inevitably influence digital trade,²²⁴ as will be discussed in the next section.

1.4.3. International regulation of the digital economy

1.4.3.1. Regulation of cross-border data flows

1.4.3.1.1. Data protection

Data management is a new feature of the digital economy. The change in the value structure, the measurement of the potential value of data and the increase in the weight of digital services in production are new challenges for regulators. The growth of cross-border data flows raises the issues of data localization and extraterritorial application of legislation on personal data protection, emphasised in Section 1.7.5. Countries and international institutions are concerned about ensuring personal data protection not only in their own territories but also in cross-border data transfers. However, according to some estimates, the negative effects of data flow restrictions on economic growth outweigh all positive effects of data protectionism.²²⁵ The possible potential costs of data flow restrictions, particularly data localization requirements, include limited access to digital commercial networks, limited abilities for companies to work with Big Data and a negative influence on the productivity and competitiveness of companies.²²⁶

The EU has adopted some of the most advanced rules on cross-border data flows, and also promotes its approaches abroad.²²⁷ The two main regulatory acts are the Regulation on the free flow of non-personal data²²⁸ and the General Data Protection Regulation (GDPR).²²⁹ Thus, the EU provides for regulatory approaches to both personal and non-personal data.

The Regulation on non-personal data ensures the free flow of non-personal data across borders (the ability to store and process data in any EU country); the accessibility of such

227 See e.g. Horizontal provisions for cross-border data flows and for personal data protection (in EU trade and investment agreements), available at: http://trade.ec.europa.eu/doclib/docs/2018/may/tradoc_156884.pdf.

228 Regulation (EU) 2018/1807 of the European Parliament and of the Council of 14 November 2018 on a framework for the free flow of non-personal data in the European Union.

229 Regulation (EU) 2016/679 of the European Parliament and of the Council of 27 April 2016 on the protection of natural persons with regard to the processing of personal data and on the free movement of such data, and repealing Directive 95/46/EC (General Data Protection Regulation) // Official Journal of the European Union. 2016. L 119/1.

data for regulatory control (competent authorities retain access to data even when they are located in another state or processed in the cloud); easier switching between cloud service providers (by encouraging the development of self-regulatory codes of conduct); and full compatibility and synergy with cybersecurity measures.

Nevertheless, the following issues – essential for the data economy as identified by the European Commission – are not yet comprehensively addressed:

- data access and transfer (whether ‘ownership’ rights exist on non-personal data generated as part of a business process or *de facto* in the possession of a business; the conditions of usability and access to such data);
- liability (how to provide certainty to both users and manufacturers of data technologies and services in relation to their potential liability);
- partially – portability, interoperability and standards (how non-personal data exchange and competitive data markets could be stipulated).²³⁰

The reason for that lies in differences in market maturity, among other issues. Barriers for data flows have been largely identified and narrowed down to the forced storage or processing of data within a geographical area or IT environment.²³¹ The implications of other data issues are not yet clear and they have a different source: “disruptive business models emerging from the digital transformation of the industry, technological advances and a fast-evolving data market.”²³²

The GDPR is aimed at giving greater control to individuals over their personal data, simplification of the regulatory environment for international business and the improvement of business opportunities by facilitating the free flow of such data. However, the GDPR has a considerable impact on third countries, which is often negative especially in the case of less developed countries. There are clear economic and trade opportunities for less developed countries, especially those relying on exports of services: restrictions on data flows affect them in particular.²³³ This is due to the high compliance costs with the new requirements as data restrictions raise the cost of the trade transactions.²³⁴

The extraterritorial reach of EU regulations for the provision of international services is a technique to impose EU requirements abroad, the inclusion of equivalence clauses being an example of the requirements’ inherent flexibility.²³⁵ The existence of inter-

235 Joanne Scott, ‘Extraterritoriality and Territorial Extension in EU Law’ (2014) 62 *American Journal of Comparative Law* 87, 117.

national commitments taken by the third country is one of the factors considered by the EU Commission to verify whether there is an adequate level of protection for data flows.²³⁶ However, this flexibility may allow a certain degree of inconsistency in the EU evaluation, which is essentially unilateral.

Box 1 – India and EU Privacy Regulation

India is an important exporter of software and IT-enable services. Most part of the provision of those services is cross-border and a smaller fraction is provided through the presence of a company (investment) or individuals outside India.

The EU has not deemed India's privacy legislation adequate according to its required levels. India has consciously chosen a balance that emphasises economic and trade opportunities over privacy. As an example, it is considered that the access to consumer credit history facilitates the provision of and resort to financial services, as digital inclusion is key for poor Indian citizens.

The enactment of a stringent national law in India would also submit all domestic companies to the same requirements, which is costly. The adoption of specific schemes (Binding Corporate Rules-BCRs and Standard Contractual Clauses-SCCs) is extremely expensive and takes time to implement. The result is that India's international trade is severely restricted due to EU rules.

Source: Adapted from Mattoo and Meltzer (2019).²³⁷

Therefore, the balance between data protection and trade promotion has not yet been effectively sorted out on the global or regional level. This is especially vivid in the example of mixed data sets. Most of the times data sets consist of both personal and non-personal data with the prevalence of the latter. Application of stricter personal data rules to such sets of data can limit economic effects and will have a particularly adverse effect on developing countries and smaller companies to comply with such rules. The EU's internal approach, for instance, is to apply personal or non-personal rules respectively in case such data sets can be easily separated.²³⁸ However if such data are inextricably linked, the non-personal rules "shall not prejudice the application of the [GDPR]."²³⁹

The fact is that data protection legislation affecting international trade has to adhere to WTO rules. Brazil, India and South Africa are founding members of the WTO, since 1 January 1995; China acceded on 11 December 2001 and Russia, on 22 August 2012. All BRICS countries are now WTO members and subject to WTO agreements.²⁴⁰ Although Russia has transferred part of its regulatory competences to the Eurasian Economic

²⁴⁰ Marrakesh Agreement Establishing the WTO (15 April 1994).

Union,²⁴¹ the rules adopted on the supranational level must still conform to WTO law.²⁴²

However, WTO rules are organised in the categories of “goods”, “services” and “intellectual property” and data flows challenge those categories, as argued in section 1. This framework was inherited from the Uruguay Round, one of the most difficult and complex negotiations that have ever taken place. All the trade commitments and concessions followed those categories and are reflected in the so-called *schedules*. The founding rights and obligations of national treatment, most favoured nation and reciprocity refer to them. This took place though before the digital revolution. Through path dependence, international governance still uses those categories even in the new regional trade agreements, but there are visible changes, such as the e-commerce chapters, as will be seen.

Beyond the GATT,²⁴³ the WTO rules have acted as “enabling data flows by liberalising infrastructure” by initially boosting value chains for IT trade through the Information Technology Agreement.²⁴⁴ Moving forward, rules that impact international trade of “smart goods” – incorporating data flow-dependent services (e.g. smartphone, Internet of Things) – might also be subject to the WTO regulation of services²⁴⁵ and intellectual property.

Breaches in the WTO rules may arise from *de jure* discrimination (e.g. local data storage or production requirements) or *de facto* discrimination (e.g. privacy or data protection laws to protect citizens) resulting from measures that limit the ability of data to move globally.²⁴⁶ In this line, it is argued that some aspects of data protection and firewall legislation do not comply with the General Agreement of Trade in Service – GATS rules.²⁴⁷

241 Eurasian Economic Union (EAEU) is an international organization of regional economic integration that seeks to create a common market for goods, services, capital and labour. It has been established on 1 January 2015 and the member states are Armenia, Belarus, Kazakhstan, Kyrgyzstan and Russia. See <http://www.eaeunion.org/?lang=en>.

Table 1.4 Possible Breaches and Defences in the GATS

Provision	Examples of Breach	Possible Defences
Most favoured nation treatment – Art. II	<i>De facto</i> discrimination among WTO members in relation to data flows	- Public morals or public order – Art. XIV (a) - Secure compliance with laws and regulations Art. XIV (c)
Mutual recognition – Art. VII	Not providing adequate opportunities for negotiation of mutual recognition agreements concerning data	(i) prevent deceptive or fraudulent practices (ii) protection of the privacy of individuals
Market access limitations – Art. XVI	Ban on cross-border transfer of data – equivalent to a ban in the provision of certain cross-border services (<i>zero quota</i>)	PLUS (chapeau) art. XIV no arbitrary or unjustifiable discrimination or disguised restriction - Security exception (essential security interests) ²⁴⁸ – Art. XIV <i>bis</i>
National treatment – Art. XVII	<i>De jure</i> differential data treatment related to national compared to foreign produced services	

Source: Adapted from Mattoo and Meltzer²⁴⁹ and Sen²⁵⁰

States with data legislation and firewalls may justify their measure using the defenses, as stated in the third column of Table 1.4.. However, they face the high hurdle of the test of the *chapeau* of art. XIV: all the restrictive data measures have to be consistently applied among the WTO members. A state cannot condition market access to the requirements of regulatory cooperation, if this is not done consistently.²⁵¹ The takeaway is that whenever states desire to use regulatory cooperation as criteria for allowing data flows, they must ensure an objective and coherent determination of the outcome of the cooperation (e.g. actual treaties or effective assurance mechanisms).

1.4.3.1.1.1. Economic regulation

The current status of international governance in data flows connects to the regulation of trade in goods, services and intellectual property as seen above. Domestic laws, regulations and requirements on data cannot result in discrimination among foreign digital

248 Most recently, the WTO Panel has decided that the national security exception in the GATT art. XX is not self-judging but requires an objective assessment of the circumstances and has to be done in good faith. WTO, Russia: Measures Concerning Traffic in Transit – Panel Report (5 April 2019) WT/DS512/R [7.102-7.104]; [7.132]-[7.135] and [7.138-7.139].

249 Mattoo and Meltzer (n 16) 777-782.

250 Sen (n 26) 336.

251 WTO, Argentina: Measures Relating to Trade in Goods and Services – Report of the Panel (30 September 2015) WT/DS453/R [7.761], [7.764]. The AB analysis is more ambiguous, since likeness between non-cooperative and cooperative countries was not established. WTO, Argentina: Measures Relating to Trade in Goods and Services – Report of the Appellate Body (14 April 2016) WT/DS453/AB/R.

goods (e.g. “smart goods”) or between foreign and national digital goods.²⁵²

When it comes to the conformity of these measures with the GATS market access and national treatment provisions, the first step is to figure out whether these new digital services are already included in the schedules, as a technology neutrality argument would suggest.²⁵³ Countries only classified and divided the different services in the schedules of the GATS for the purposes of liberalisation. A functional approach to the classification of services – focussed on the function achieved by the service – leads to more legal certainty and constructive liberalisation of services.²⁵⁴ In this regard, there are truly no new services, but just different ways to supply the service and the debate should focus on whether the data regulatory measure affects the supply of services, even if it regulates digital goods.²⁵⁵ In any case, an amendment in the WTO classification system – for example, to CPC Version 2.1 – might provide clarity to determine the sectors to liberalise in the future.²⁵⁶

Beyond the *status quo*, some solutions for the economic regulation of data flows under the framework of the WTO have been put forward and include:

- Recognition Agreements: GATS art. VII – members’ recognition of the protection standards of the others on a bilateral basis;
- Offering transparency and predictability on data flows as additional commitments: GATS art. XVIII – members’ unilateral offer;
- Common principles incorporated in a WTO Reference Paper on Privacy – similar to the *binding* WTO Telecommunications Paper.²⁵⁷

A way forward to address the regulation of data flows under the framework of the GATS WTO is the use of a data differentiated approach. GATS commitments do not differentiate between the types of data flows inherent to the provision of services. Thus, this approach involves different regulation according to the type of data (e.g. personal data, company data, business data, social data). Greater liberalization could ensure market access and national treatment for some types of data (e.g. company data) while maintaining regulatory autonomy in relation to other types of data (e.g. personal data). This could be achieved by the assumption of horizontal commitments in the schedules on certain types of free data flows, as suggested by Sen.²⁵⁸

There are several common justifications for data localisation measures, among them:

252 GATT art. I(1) and art. III(1) c/c III(4).

253 WTO, US: Measures Affecting the Cross-Border Supply of Gambling and Betting Services – Report of the Panel (10 November 2004) WT/DS285/R [6.285]. See also WTO, China: Certain Measures Affecting Electronic Payment Services – Report of the Panel (31 August 2012) WT/DS413/R.

258 Sen (n 245) 343–347.

foreign surveillance, domestic law enforcement, individual privacy and security, economic development and internet control.²⁵⁹ However, from the point of view of international trade governance, data localization is seen more as a barrier to digital trade than an instrument of jurisdictional control. The restriction of internet access and data flows to protect domestic companies is often seen as a form of digital protectionism.²⁶⁰ A change in this mindset would require an adjustment to the current rules. A ban on localization measures could be incorporated as an horizontal or additional commitment in the schedules of the WTO members that desire to do so, to signal credibility towards other members.

Box 2 – Russia and data localisation.

Russia's requirements on local storage of data are in force since 2015. The data localization provisions may have been driven by national security and fiscal objectives. There are important costs for their implementation involving the adaptation of infrastructure of companies, but it is still debatable whether it substantially enhances security and protection of data subjects or imposes losses to the economy²⁶¹. *LinkedIn* was blocked in Russia due to the failure to comply with those requirements.

Since its WTO accession, Russia liberalised the relevant sectors under the GATS agreement as there are no limitations on market access for digital, IT or data storage, processing and transmission services in Russia *schedules*. Therefore, some have sustained that there may be a potential violation of national treatment and market access obligations.

The exceptions in the GATS require that the stated goals of the measure (protect citizens' data from unlawful access) are actually achieved, which is debatable as there is no prohibition to transfer the data abroad. Some argue that it must be established that the storage inside the country is more secure than outside for the GATS exception to apply.

Source: Sen²⁶²

As WTO rules and trade agreements regulate "intellectual property" they also shape the regulatory environment of data flows.²⁶³ The TRIPS²⁶⁴ requires members to ensure the protection of copyrights, patents, trademarks, layout-designs of integrated circuits and undisclosed information. Intellectual property chapters in trade agreements may include "TRIPS-plus" and "TRIPS-extra" provisions, such as ensuring the implementation of technical protection measures (TPMs) and the responsibility of internet service providers.²⁶⁵ Company data is usually protected by intellectual property rights such as trade-

mark and trade secrets.²⁶⁶ For example, the CPTPP highlights the protection of trade secrets “including by means of a computer system”.²⁶⁷ This may be further regulated by cybersecurity laws. However, BRICS countries do not seem to play a major role in those new initiatives and have generally been defensive when it comes to intellectual property protection.

Box 3 – China Cybersecurity Law in the WTO

China measures adopted and under development relating to its Cybersecurity Law have been discussed in the WTO Council for Services throughout 2018 and 2019. Jurisdictions such as the United States, Japan and the EU have sought clarification due to its possible adverse effect in services supplied through a commercial presence and on a cross-border basis. Members have sought explanation on the conformity with the GATS of the obligation of foreign operators to store data domestically and to conduct security assessment on cross-border transfers. Members are unsure about the meaning of legal terms such as “critical data” and “critical information infrastructure”.

On the other hand, China has argued that it faces great challenges to national cybersecurity and aims to protect societal public interests. China is still in the process of drafting and implementation of its domestic framework and is ready to receive suggestions and inputs.

Source: WTO Council for Trade in Services – Report of the Meeting 7 December 2018 – S/C/M/137

Another recent topic that touches upon international economic regulation is the range of issues arising out of the trade war between China and the United States. They have changed the dynamics of international digital governance, and consequently, data governance. As the two major world trade powerhouses, both countries are more than able to set a bilateral governance system to rule their relations, to the detriment of the World Trade Organisation forum. The trade frictions of the last five years reached a peak stage of tit-for-tat retaliation. This involved all the repertoire of trade relations and sanctions (trade in goods, trade in services, investment and intellectual property) and has an important digital component, as highlighted in Section 1.7.8.

Box 4 – Trade war and restrictions to investments

A special chapter of that trade war is the US decision to ban Huawei’s equipment from its networks. As a result, Google had to pull Huawei’s Android licence. While Android would still run on Huawei’s phone, Google would not provide technical support and collaboration for Huawei phones. There are obvious implications for competition from the decision of Google not to pair with Huawei. This may lead to an impairment in innovation to the detriment of consumers, for example, in the design of smartphones. However, the latest developments of the trade talks between both countries is that US will issue special licences for companies that want to trade with Huawei.

²⁶⁶ Sen (n 245) 345.

²⁶⁷ Comprehensive and Progressive Agreement for Trans-Pacific Partnership (signed 8 March 2018) – CPTPP art. 18.78.

This might mean that Google may be able to apply for this special licence. In the UK, the authorities considered that there were no grounds to prevent Huawei from getting involved in its 5G networks, despite of US pressure.

Source: That Global Ban on Huawei? Not So Much Anymore WIRED <https://www.wired.com/story/global-ban-huawei-not-so-much/>

1.4.3.2. International regulation of digital consumer protection

Although e-commerce is gradually absorbing traditional trade, trade via traditional channels is still dominant. Nevertheless, there is a trend showing the outflow of consumers from traditional trading centers to online platforms, which is also true for BRICS countries. For example, in Russia in 2018 the growth in B2C sales through digital trade channels was 22%, and the growth of purchases through foreign internet platforms was 24%.²⁶⁸

E-commerce chapters in trade agreements also affect the regulation of data flows. Reflecting the lack of progress of the WTO in the area,²⁶⁹ they highlight the non-differentiation of treatment between digital products and their offline equivalent and include a duty free moratorium on international trade by electronic transmission. They may also include rules related to IT standards and interoperability, cybersecurity, payments and electronic signatures and establish a common ground for the digital marketplace, such as the fair use of the internet for e-commerce, network neutrality and restrictions on data localization and no requirement of transfer of source codes.²⁷⁰

It is in those chapters that the international governance of digital consumer protection is found. A system of governance for e-commerce depends on building online trust: increased consumer confidence will stimulate cross-border electronic transactions.²⁷¹ Global regulation for digital consumer protection would naturally contribute to system-wide trust.²⁷² As most consumer protection is nationally enforced, international regulation will promote convergence between national protection standards, identify functional equivalence or compatibility or promote cooperation between enforcement agencies.

The nonexistence of WTO regulation on consumer protection does not mean that the topic is not discussed in the e-commerce negotiations, as noted above. In this forum, some WTO proposals on online consumer protection were brought. Russia, for instance,

268 Rynok elektronnoi trgovli v Rossii: sostoyanie i prognoz 2014-2018 [E-Commerce in Russia: Status and Forecast 2014-2018]. 271 Sen (n 26) 345.

272 Ioannis Lianos and others, 'The Global Governance of Online Consumer Protection and E-Commerce: Building Trust' (World Economic Forum 2019) White Paper.

has expressed interest to ensure security of cross-border e-commerce and to create a digital platform to share information on unsafe online goods and services. It has also recognised the importance of agency cooperation to prevent dishonest activity in e-commerce.²⁷³

The topic is therefore considered to be “WTO-extra”. In this regard, regional agreements may encourage or incentivise regulatory convergence for the protection of consumers between the jurisdictions involved; commitments on cooperation among consumer agencies can also be present in those agreements.²⁷⁴ A component of that cooperation could take the form of technical assistance from better developed jurisdictions towards less developed ones.²⁷⁵ Consumer protection provisions may be powerful and truly precipitate change in domestic policies, although this highly depends on how they are phrased.²⁷⁶ Soft law initiatives may shape convergence of principles in a move towards “principles-based” consumer regulation on a global level; this is in consonance with dynamic performance standards and the interaction between traders and regulators in light of technological developments.²⁷⁷

1.4.4. Prospects for the future: global digital regulation and competition policy

The long-term trend in digital trade is erasing the boundaries between goods, services and intellectual property. More goods are being sold bundled with a mandatory set of services, which effectively constitute the main object of trade. In addition, digital twins are becoming a type of good. In essence, we are moving from the consumption of goods and services to the consumption of technologies, which determine the value of services regarding the usage of goods. Profound changes are also taking place in the value chains: new models provide for “compression” of trade value chains, reduction of the number of intermediaries between consumers and producers, and transformation of the internal processes of all participants in the supply chain and marketplace. Markets are increasingly dominated by global ecosystems, and consumers are progressively more active participants in digital trade. Data is effectively becoming the new fuel of the global economy. These changes raise profound regulatory challenges for global digital trade and cross border data flows, where regulators must confront competing interests including those revolving around data protection and economic development.

Some are incredulous of the suitability of trade forums such as the WTO to regulate digital trade issues – and consequently, data issues – and recognize its inherent limitations.²⁷⁸ On the other hand, international trade governance has achieved a great deal of institutionalization and some results in terms of enforcement. It would be unwise to avoid exploring the potential of this forum to set and enforce rules, in favour of “soft

277 Lianos et al. (n 69) 11–12; 17.

278 Burri (n 36) 129.

law” alternatives or principles or private standards.

In any case, regulatory cooperation seems to be the way forward for the governance of the digital economy and regional trade agreements may be laboratories for interaction.²⁷⁹ New approaches can be found in the CPTPP and in the new US-Mexico-Canada agreement. Those solutions may constitute points for convergence for future regulation. This requires a parallel agenda on building up the confidence of domestic regulators to allow data to leave the jurisdiction without undermining regulatory goals.²⁸⁰ Alternatively, one could say “multilateralism” and “regionalism” may not work well for the digital economy and “unilateral” approaches coupled with “bilateral” recognition agreements could provide the basis for a pragmatic and reciprocal approach for economic cooperation. However, there is a strong claim that the model for the future will not be based on unilateralism but on persuasion and a global community of shared approaches with a structured engagement for coordination and harmonization: the future of data trade will turn on concessions and compromise.²⁸¹

It is hard to know which model would fully reflect the interest of the BRICS countries, as they are the ones that have adopted some of the data measures under international scrutiny (see Boxes II and III), though some may lose out from data restrictions imposed by other countries (see Box I). The cautious approach by the BRICS countries to embark on these initiatives may change. The dynamic needs of the digital economy in those countries could soon shape a new common discourse in the area.

1.5. A brief description of digital technologies

1.5.1. Artificial Intelligence

In 2016 the founder and executive chairman of the World Economic Forum Klaus Schwab named AI as one of the main forces of the fourth industrial revolution.²⁸² According to some calculations, the GDP growth contribution of AI will be no less

279 *ibid* 132.

280 Joshua P Meltzer, ‘Governing Digital Trade’ (2019) 18 *World Trade Review* S23 48. governments and regulators have to determine how to benefit from these developments while maintaining the integrity of their domestic regulations. Currently, governments are increasingly restricting global data flows and requiring data localization, undermining the economic benefits of digital trade. To address this trend will require a system of digital trade governance that has two key elements. One element is new digital trade rules, some of which exist in the WTO and others which are being developed in free trade agreements. The other is international regulatory cooperation to develop standards and mutual recognition agreements in areas such as privacy and consumer protection that gives domestic regulators confidence that allowing data to leave their jurisdiction will not undermine achievement of domestic regulatory goals. In the absence of such regulatory cooperation, governments are likely to continue to restrict data flows, relying on the exceptions provisions to their digital trade commitments.»»DOI»:»10.1017/S1474745618000502»,»ISSN»:»1474-7456, 1475-3138»,»language»:»en»,»author»:»[{«family»:»Meltzer»,»given»:»Joshua P.»}],»issued»:»[{«date-parts»:»[[«2019»,4]]}],»schema»:»https://github.com/citation-style-language/schema/raw/master/csl-citation.json»}

than 5% in 2030, and much larger in the case of more advanced countries.²⁸³ Opportunities are many, sometimes not even foreseen, however, there are also multiple challenges (such as ethical, legal and cybersecurity), which depend on our ability to understand, control and predict AI-based systems.²⁸⁴

To address both opportunities and challenges, many jurisdictions have adopted strategies of AI development.²⁸⁵ The BRICS countries have also been working in this direction. In 2017 China adopted one of the most comprehensive strategies “A Next Generation Artificial Intelligence Development Plan” setting out an ambition to lead the world in AI by 2030.²⁸⁶ India in its 2018 discussion paper on AI strategy is focusing on leveraging AI not only for economic growth, but also for social inclusion (“AI for all”).²⁸⁷ Russia, Brazil and South Africa do not yet have dedicated AI strategies. However, Russia is actively working on its national strategy on AI development.²⁸⁸ The Brazilian digital transformation strategy “E-Digital” of 2018 addresses digital transformation, including AI.²⁸⁹ South Africa’s “Intsimbi Future Production Technologies Initiative” launched in 2018 with the aim of advancing South Africa’s manufacturing sector also considers AI.²⁹⁰

There are various ways to define AI; one is proposed by Stuart Russell and Peter Norvig as “the designing and building of intelligent agents that receive precepts from the environment and take actions that affect that environment.”²⁹¹ AI dates back more than half a century (see Figure 1.14.), and its history saw both peaks of interest and almost full disappearance thereof. The rather recent increase in interest in AI is due to the developments in machine learning, advances in computing power, and data availability, which ensure the effective work of artificial neural networks on a large scale. Thanks to that, it is often possible to ensure attaining results without developing specialized software to solve a particular problem, including carrying out certain tasks to which there is no algorithmic solution, or which are hard to accomplish otherwise.

Figure 1.14. AI timeline

Source: <https://www.innovationobservatory.com/node/243>.

The development of AI strives to transfer high-level processing of data from human beings to computers. AI can be used in order to find unobvious or hardly cognizable dependencies and patterns where it is difficult or unfeasible for humans to perform, as well as to run routine intellectual operations or labor-intensive transformation of information. At the same time, AI-based systems cannot currently provide substantial responses on the essence or cause-and-effect relationships of phenomena.

AI is commonly divided into two groups: artificial general intelligence,²⁹² or "strong AI",²⁹³ and applied or "weak AI". The former is a hypothetical artificial intelligence capable of performing any intellectual task and set its goals independently. It is therefore either comparable to human-level intellect or surpasses it. There is no technology close to it currently available, but there are no conclusive theoretical limitations for it to appear in the future. Availability of strong AI will have an unlimited scope of application. Weak AI, on the other hand, are applied systems designed to address specific tasks. Broadly speaking, these are all AI solutions available today. They are sometimes subject to the so called "AI effect" problem: as soon as a certain inconceivable result is achieved using AI, such a task is no longer considered an AI task. John McCarthy stated that "[a]s soon as it works, no one calls it AI anymore."²⁹⁴

1.5.2. Machine Learning

Machine learning is one of the AI methods and deep learning is correspondingly a subset of machine learning (Figure 1.15.). Machine learning has become the major technological approach that defines the current state of AI. The essence of the technology is the creation of a database of study examples that a computer aligns to (self-learns), produces the rules, and therefore can correctly recognize and classify new incoming data. Thus, it is an ensemble of algorithms and approaches that allow computers to make conclusions on the basis of available data. Adding more study examples improves recognition results. The major technology behind it are artificial neural networks, which are statistical modelling techniques capable of learning sophisticated relationships, i.e. they modify their own code to find and optimise links between inputs and outputs.²⁹⁵

Figure 1.15. AI Mind Map

Source: Samrat Kar, AI Mind Map, available at:

<https://medium.com/ml-ai-study-group/ai-mind-map-a70dafcf5a48>

An example of considerable breakthrough in machine learning is Google DeepMind's AlphaGo, which was won by the South Korean Go champion Lee Sedol.²⁹⁶ Go is considered to be the most complex game in the world. Achieving this result was possible by using *deep learning* and *reinforcement learning*. Deep learning is applied to the learning methods of neural networks that use more than one buried layer, and therefore formally the word "deep" also indicates the multi-layer architecture of the neural network. Algorithms of this kind appeared long ago, but the computing power was low and could simulate only several hundreds of artificial neurons with one buried layer between input and output layers. Currently, for instance, voice recognition systems use up to 12 internal layers of neurons.

²⁹⁵ OECD (2019), Artificial Intelligence in Society, OECD Publishing, Paris, <https://doi.org/10.1787/eedfee77-en>, p. 28.

²⁹⁶ The Google DeepMind Challenge Match, AlphaGo, March 2016, available at: <https://deepmind.com/research/alphago/alphago-korea/>.

The uniqueness of deep learning is that the machine finds features on its own (key traits, which allow it to distinguish different classes of objects more easily) and structures such features hierarchically: simpler features make up more complex ones. There is no formal definition of deep learning as it combines a whole range of different technologies. Its feature is that it can cope with noisier data by increasing significantly the number of neural layers and neurons and the amount of data.²⁹⁷ In other words, deep learning is an analysis of previous and current data for the purposes of forecasting the future. Reinforcement learning, on the other hand, focuses on experience-driven sequential decision-making, meaning that agents take action to maximise a cumulative reward.²⁹⁸

Therefore, a computer learns on the examples and its own experience. For instance, AlphaGo first analysed 29.4 million moves and 160 thousand games of professional players and two copies of the programme started playing between each other adding more games to the study sample. Having played millions of games, the programme learned to assess the most beneficial placing of stones on the board to ensure victory.

Deep learning can be supervised and unsupervised. Supervised deep learning envisages compulsory learning using examples or learning samples. Unsupervised learning means that an AI-based system searches on its own. Initially, the former has been giving better results. Nevertheless, the prospects of the latter are higher as developers do not need to prepare the data and learning is not limited to available datasets. Thus, AlphaGo Zero using reinforcement learning and not using datasets derived from humans trained itself faster and was able to beat the original AlphaGo by 100 games to 0.²⁹⁹

Deep learning is currently part and parcel of research in voice recognition, image recognition, self-driving, medical state diagnostics and performing other complex tasks. Nevertheless, AI technologies using machine learning have distinctive features and limits. One of those is the inability of a machine to reconstruct the logic of adopting this or that decision. It limits substantially the application of AI in socially sensitive and strategic fields. Apart from that the success often depends on access to sufficient Big Data for learning (see the following section). A separate group of risks is related to the way the initial learning data is formed, which can include trends provoking displacement of the focus of decisions. There are some other technical problems inherent in machine learning which must be taken into account in the practical implementation of AI.

1.5.3. Big Data

Big Data represents a new scale of datasets so voluminous that they exceed classical tools of analysis. The amount of data added to the global dataset every day is quantifiable at around 2.5 quintillion bytes per day³⁰⁰ on average and this number continues to grow. Consequently, it is extremely difficult to precisely define Big Data, as the relativity and changing aspect of this new scale of dataset make any order of magnitude or characteristic quickly obsolete. If the term “Big Data” dates from 1997 according to the Association for Computing Machinery,³⁰¹ the definition recognized by most scholars and business today is Gartner’s (2001): Big Data is “high-volume, high-speed and/or high-variety information assets that demand cost-effective, innovative forms of information processing that enable enhanced insight, decision making, and process automation.”³⁰² Gartner’s definition is based on the enunciation of three broad dimensions of data processing, also called the 3 Vs, that help to understand the outlines of Big Data:

1. *High Volume*: It is the increase and significant size of the data volume that differentiates Big Data from conventional data analysis. This volume dimension is often considered to be the most relative. For instance, worldwide digital data have grown from 1.2 zettabyte³⁰³ per year in 2010 to 1,8 zettabyte in 2011, then 2,8 zettabytes in 2012 and will rise to 40 zettabytes in 2020.³⁰⁴
2. *High-Variety*: In addition to a quantity of information that surpasses conventional data analysis tools, the format of these data is also very different. These are not traditional relational data. These data are raw, semi-structured or even unstructured. These are complex data from web mining, text mining and image mining. Thus, these new and extremely varied forms of data cannot be treated with traditional tools directly.
3. *High-Velocity*: These growing data streams are in perpetual development and require real-time processing to avoid the obsolescence of the statistics obtained. This dimension can have a major importance in the treatment of Big Data by the stock market for example. In fact, computers that send purchase orders automatically must benefit from the information collected in real time to minimize the risk.

300 B. Marr “How Much Data Do We Create Every Day?”, Forbes.com, 21 May 2018, <https://www.forbes.com/sites/bernard-marr/2018/05/21/how-much-data-do-we-create-every-day-the-mind-blowing-stats-everyone-should-read/>

301 G. Press, “A Very Short History Of Big Data”, Forbes, 9 may 2013, <https://www.forbes.com/sites/gilpress/2013/05/09/a-very-short-history-of-big-data/#69c1ed6465a1>

302 D. Lanney, “Application Delivery Strategies”, <https://blogs.gartner.com/doug-lanney/files/2012/01/ad949-3D-Data-Management-Controlling-Data-Volume-Velocity-and-Variety.pdf>, Meta Group, 6 February 2001

303 1 Zettabyte equals 1,000,000,000,000,000,000 bytes.

304 J. Gantz. and E. Reinsel. 2011. “Extracting Value from Chaos”, IDC’s Digital Universe Study sponsored by EMC, 2011 <https://www.emc.com/collateral/analyst-reports/idc-extracting-value-from-chaos-ar.pdf>

Nevertheless, depending on their use of Big Data, companies, communities or researchers who use them accentuate the importance of one dimension or leave others on the side, and can even highlight the importance of new ones. That is the case with the growing importance of veracity³⁰⁵ and value³⁰⁶ that are new axes of definition and stakes of Big Data with the rise of fake profiles and fake information on the Internet.

Thus, all these dimensions are constitutive of Big Data's specificities. But these specificities are also the main issues in order to stock and use these complex data for the actors who wish to take advantage of the situation. Given the extent of the Big Data components, the benefits are multiple and form various activities.

Research is at the origin of Big Data analysis, and science benefits from it particularly. In medicine, for example, Big Data now makes it possible to decode the human genome in less than a day while it took 10 years to achieve it up to 2003.³⁰⁷ More recently, a Korean Project developed by the Korea University Medical centre started to be tested in hospitals in order to create a cloud based system to turn dispersed medical information into Big Data. This project is expected to cut the operation cost to one fifth and to help hospitals treat patients more efficiently. It shows how Big Data can both contribute to research at the very beginning of the scientific process but also at the very end, the individual scale.³⁰⁸ Other fields such as astronomy, aeronautics or meteorology also benefit heavily from the recurring patterns enlightened by the huge dataset that Big Data provides.

Big Data proves to be a formidable political weapon to understand voters' wishes during campaigns but also to highlight social media trends, target action plans more efficiently or even as part of monitoring and security procedures.³⁰⁹ For instance, in India, Big Data was used for the Bharatiya Janata Party for the 2004 elections campaign. Later on, Narendra Modi, the Indian Prime Minister even quoted Facebook as an inspiration. His move toward the mastery of Big Data is blatant with Aadhar: an ID system for India's 1.3bn residents that is required for almost every government service and which allows the state to use efficiently the citizen's profile with information at high rate of veracity.³¹⁰ However, the impact of data on modern elections is an issue everywhere on the planet, which has been underlined by firms like Cambridge Analytica Ltd and the scandals linked to it. Even if

the direct impact of Cambridge Analytica on elections is still unclear, the fact that it has been involved in elections in Kenya, United Kingdom, Malta, Mexico, India, Australia, and the US, it shows how important data management and analysis has become in politics.³¹¹

Big Data is of paramount importance in the analysis of actions and behaviors and generates a boost of progress and production which gives the information a value in constant increase. According to the International Data Corporation, the weight of Big Data in the global market in 2020 is estimated at \$203 billion.³¹² Moreover, it is no coincidence that seven of the ten largest companies in the world in terms of market capitalization are technology companies and five of them (Amazon, Alphabet, Facebook, Alibaba, Tencent) rely massively on data treatment, mining and selling.³¹³ Big Data also enabled the elimination of intermediaries with the example of NATUs (Netflix, Airbnb, Tesla, Uber) and even Spotify that use Big Data to understand and adapt to customers behavior and thus reduce price by replacing human intermediaries.³¹⁴ Big Data affects many areas of the private sector, such as sports,³¹⁵ insurance³¹⁶ or the energy sector³¹⁷ where collecting data could improve performance and yield.

Nevertheless, the problems associated with Big Data are as numerous as its fields of application. It is therefore important to mention some of them briefly. The first and most well-known is data mining and the threat to privacy that it generates. Indeed, regulation of data protection is still developing and knowing that data is easily duplicable and usable by more than one person, it is difficult to assess who owns it and how. Snowden's revelations have generated an awareness at this level that has triggered a reaction by the public and the law.³¹⁸ Moreover, if the data are exploited more and more precisely, they become all the more valuable. Cyber security is therefore involved in all aspects related to Big Data. The last breaches of giants like Facebook in 2019 are highly publicized and quickly corrected, but the

data of hospitals, universities or small companies are much more vulnerable.³¹⁹ Entropy and the growing volume of data is also an issue as the Big Data collected lacks density. It means that only a minor part of Big Data is actually relevant and usable to draw trends and that the rest is not exploitable. All the inaccurate and unusable data contribute to “information overload” and “infobesity” and reduce the yield of Big Data analysis.³²⁰ Moreover, stocking a growing volume of potentially useless data has an important cost and environmental impact for no real return on investment. Finally, the situation of GAFAs (Google, Apple, Facebook, Amazon) raises questions as the data they collect allows them to set up economic, social and environmental actions but gives them a status close to monopoly that is hard to control with traditional antitrust procedures.³²¹ Thus, transparency, security and control seem to be the major challenges for big data now and in the near future.

1.5.4. Smart Data

It is important to understand that Big Data and Smart Data are not really two opposite concepts, but rather complementary. Smart Data is a way to explore and engage with the wideness of Big Data with a more strategic and restrictive approach. Indeed, the collection of Big Data makes it possible to benefit from a non-negligible sample of information but does not guarantee density and exploitability. Thus, the advantage provided by the volume dimension of Big Data disappears very quickly when information cannot be exploited because of data of little interest. For instance, according to the Electronic Business Group, Micropole and Qlik, 54% of French companies cite the scarcity of profile as a brake on the development of Big Data.³²² Thus, the policy of massive storage of unprocessed data can still be seen as an investment for multinationals such as GAFAs. Indeed, these companies have the computing power to make sense of low-density data and have the means to keep unnecessary data in the short term.³²³

Nevertheless, for smaller companies or for communities with fewer resources, storage represents a significant cost that must be offset by direct data exploitation.³²⁴ Thus, these companies, for their marketing campaigns for example or for their business development prefer to set objectives prior to the collection of data.

As a consequence, we are witnessing a return to a more conventional analytics operating model where the data collected match the 3Vs of Big Data but also have a high rate of value and veracity because of the strategic research done to collect them. The strategic research to target the need of the companies before the research is the move from Big to Smart Data. The point of Smart Data is that companies or researchers no longer collect information to draw conclusions from the mass collected but pinpoint their strategic needs of information beforehand to reduce the field of collection.³²⁵

To metaphorize it, when collecting rainwater, Big Data collects all the drops where Smart Data only collects where it rains the most. This approach of Smart Data coupled with the expansion of Big Data has profoundly changed the customer relationship with the implementation of customer feedback loops. The orientation of the business model tends to change as companies tend to move progressively from a “product” business model to a “service” business model. Rolls Royce no longer sells its engines but rents them which allows the collection of various data by sensors placed in strategic spots where issues are frequent. This action allows the customer to be supported in the event of an issue in exchange for real-time information collection in order to improve quality in the long run.³²⁶ It creates a symbiosis between customers and products where both benefit from the data transfer.

Smart Data also helps to improve entire cities where people’s activities are tracked in order to improve communication or to solve their problems more efficiently. Rio de Janeiro is one of the leading figures as a “smart city”³²⁷. One of their main innovative features has been to associate with the Waze app in order to decongest the city lanes by using live data instead of urban prevision for the road network modification.³²⁸

Thus, even if Big Data makes it possible to determine major trends on a certain amount of exploitable data, the challenge of Smart Data is to perform an intermediate filtering before the exploitation of the analytics by targeting the most useful data before the research. In order to do this, smart data analysis strategies are set up in advance by managers, but this treatment and intelligent analysis of Big Data cannot be done by humans. It is in this respect that developments in AI are particularly useful and intrinsically linked to Big Data and Smart Data. Machine learning uses Big Data to benefit from its volume and extend its learning capacity.³²⁹ But

the long-term objective of the AI that is trained to do it is that they can extremely quickly sort the Big Data to deliver only the Smart Data which has a real potential of exploitation.³³⁰

Smart Data is therefore a form of continuity of Big Data but also reintroduces more traditional mechanics in the wheels. Indeed, it is a way to bring back conventional dense data analysis in an era where data is no longer directly exploitable. Smart Data is therefore the gateway through which Big Data becomes useful, intelligible and profitable for the greatest number of companies and people and not only to the internet giants.

1.5.5. Blockchain

According to a 2015 report from the World Economic Forum on breakthrough technologies and their societal implications, blockchain technology is expected to store an approximate 10% of global GDP by 2027.³³¹ It shows the potential impact such technology could have on the world economy. In Russia, the interest in blockchain and digital currencies dates back to 2016.³³² However, the legal framework still does not allow the technology to thrive. Overall, Blockchain was made widely recognizable with the 2009 creation of Bitcoin as the cryptocurrency needed a secure and decentralized system for its transactions.³³³ It was a way to move beyond the shortcomings of the existing banking system (delays for overseas transactions, commissions from the centralized institution etc.). However, the technology was available prior to cryptocurrencies as Stuart Haber and Scott Stornetta carried out a first work on a secured chain of blocks in 1991.³³⁴ Blockchain technology was defined, during the 2018 Crypto Valley Conference, as “an append-only database maintained by distributed nodes instead of central authorities.”³³⁵ In other words, the technology constitutes a distributed ledger that is completely open to anyone. It is known for its application in the framework of cryptocurrencies but it has the potential to spread in various economic sectors and is expected to bring substantial changes in the field of contractual relationships.³³⁶

The functioning of blockchain relies on five main features.³³⁷ First, blockchain is a distributed ledger, meaning it grants each party complete access to the entire database and its history. Second, it relies on peer-to-peer transmission. Instead of using a central entity to manage the chain, blockchain uses a P2P network allowing everyone to join. When someone joins the network, he or she gets the full copy of the blockchain. The node can use it to verify that everything is in order. Third, blockchain ensures transparency through a system of pseudonyms. When users make a transaction, they do it through their blockchain address which is a unique 30-plus-character alphanumeric address. It is the users' decision to actually provide proof of their identity or remain anonymous. Fourth, blockchain is able to keep its records irreversible. This is one of the major innovations of the technology. The technique is as follows: each block is identified by a hash which is comparable to a fingerprint. Blocks also contain the hash of the previous block. If someone tampers with a block, it causes the hash to change as well. It therefore shows that there are inconsistencies in the chain. Blockchain combines it with its proof-of-work mechanism that slows down the creation of new blocks. Tampering with a block becomes hard since it requires recalculating the proof-of-work for all the following blocks. Fifth, Blockchain relies on computational logic, meaning it may be run through algorithms set up by users and generate automatic transactions.

Blockchain technology is expected to substantially modify the global economy. According to the European Commission, blockchain has already "numerous applications throughout the whole lawful economy".³³⁸ The technology is expected to reinvent contractual relationships throughout its system of smart contracts. Bernard Marr explains the functioning of blockchain adapted to contractual obligations, namely smart contracts.³³⁹ As blockchain allows the storage of digital information such as computer codes, they can be set to execute only once different parties enter their keys or any other circumstances happen that have been agreed upon. The consequence is that everyone must agree that the contract has been filled and the contract immediately executes when conditions are filled. The use of smart contract is already utilized by businesses in the way they validate delivery of service for example.³⁴⁰ It is also set to expand to new areas such as distribution of electricity through "smart" local power grids.³⁴¹

Blockchain may also lead to substantial changes in the real economy as it allows parties to eliminate the “middleman” in transactions.³⁴² In accounting and banking, Bank of America, Barclays and Morgan Stanley have already announced that they will commit to the R3 CEV initiative, an informal agreement between firms committing to collaborate in investigating blockchain’s potential use in finance. Visa and MasterCard are currently exploring how distributed ledger could improve the process of cross-border payments and make it more affordable.³⁴³ Blockchain can also be used to store ID records, as it is already being envisaged by the European Commission,³⁴⁴ to include more fairness in online gaming and ensure more transparency in electoral process.

Blockchain technology is yet struggling to fulfil its potential making its future uncertain. Security of data and properties of assets raise legal issues as applications of blockchain technology in the real economy are still being experimented with and thus lack reliability. In the EU with advanced data protection rules,³⁴⁵ blockchain technology must deal with an increasingly constraining environment. BRICS countries are also seeking to build a legal environment that takes into account the implications of blockchain. Thus, the surge of investments related to blockchain in Brazil since 2015 has forced the government to adapt its national legislation.³⁴⁶ In May 2017, it established a commission to examine the existing regulation in an attempt to soften the legal framework. Overall, the technology could allow cutting costs, especially in the way information is verified. However, applying it to sensitive areas such as financial services or elections requires a centralized institution to prevent fraud which brings back the idea of an intermediary. Not to mention that unsuccessful attempts of using blockchain technology have occurred. For instance, Honduras property blockchain was announced in 2015 and finally abandoned due to official indifference.³⁴⁷ Sierra Leone used the Swiss start-up Agora to run its elections. It turned out that the company barely observed the election and provided wrong tallies. As a recent example, Stripe, a big digital-payments firm, abandoned its blockchain experiments after three years as it labelled it “slow and overhyped”.³⁴⁸

Chapter 2: Economics of Platforms

2.1. Theories of harm for multisided platforms: challenges for competition policy and BRICS answers

Svetlana Avdasheva & Dina Korneeva*

Competition authorities in BRICS countries develop theories of harm under enforcement against multisided platforms similar to the corresponding theories of the European Commission. Discrimination and tying with exclusionary effects have been at the center of investigations and decisions. Remedies in the infringement decisions are intended to protect rivalry through ‘no restriction of multihoming’ conditions. There is no evidence that BRICS authorities apply a specific economic theory of multisided platforms (MSPs hereafter). In particular, decisions typically do not identify potential efficiencies from the conduct of MSPs and do not compare losses from anticompetitive conduct with efficiency gains. However, there is no difference with mature jurisdictions in this respect.

2.1.1. Multisided platforms: increasing attention of competition policy

Multisided platforms (MSPs hereafter) are among the hot topics for managerial³⁴⁹ and economic³⁵⁰ studies during at least the last two decades. Despite the fact that network externalities, both direct and indirect (or cross-platform)³⁵¹, emerged and were studied in the pre-digital era, the importance of the issue in the digital era sharply increased. The reason is the increasing opportunities for MSPs to exploit cross-platform network externalities and obtain large profits in digital markets. Moreover, networks can form much faster than before.

* The paper is an output of a research project implemented as part of the Basic Research Program at the National Research University Higher School of Economics (HSE University). Authors cordially thank for the fruitful discussions and valuable comments Ioannis Lianos, Pierre Regibeau, Eduardo Pontual Ribeiro and the participants of 14th Annual Competition and Regulation Conference (CRESSE). All mistakes are the authors’.

349 Eisenmann, Th., Parker, G., Van Alstyne, M., 2006. Strategies for two-sided markets. *Harvard Business Review*, 84, 92–101.

350 Rochet, J. C., & Tirole, J. (2006). Two-sided markets: a progress report. *The RAND journal of economics*, 37(3), 645–667.

351 In the literature, two types of cross-platform effects are discussed. The direct network effect appears when user’s benefit from a platform is directly affected by the number of users (Katz, M.L., Shapiro, C. (1985). Network externalities, competition, and compatibility. *American Economic Review*, 75(3), 424–440). The indirect network effect means that users on one side of a platform benefit from an increase of the number of users on the other side of a platform (Armstrong, M. (2006). Competition in two-sided markets. *RAND Journal of Economics*, 37 (3), 668–691).

In recent years, there has been a prominent increase in the platform economy. In its 'Technology Vision 2016' report, the global consulting firm Accenture argues that 'unparalleled growth of the digital economy has put it on course to account for 25% of the world's entire economy by 2020, up from 15% in 2005. Platform business models represent a fast-increasing proportion of the overall total'³⁵².

Platform-based companies both create new markets and transform existing downstream markets. Big data represents a particular resource of platforms since it attracts the large number of customers. Processing of big data allows platforms to improve its own decision-making (e.g. to develop a price discrimination scheme) or to improve services for customers (e.g. targeted advertising). Big data may result in a more efficient management of resources that could provide annual net savings of up to €600 billion for EU enterprises. Digital platforms may capture 30–40% of the value created in the industrial chain³⁵³.

However, along with the enhanced resource efficiency, the large size of MSPs may cause a strong impact on competition in platform and downstream markets³⁵⁴. In their value chains, large MSPs act as dominant players ('lead' firms in the sense used by the theory of global value chain)³⁵⁵. Governance in value chains represents not only rule-setting and enforcement but also reallocation of value created in the value chain in favour of the dominant participant. The share of value distributed towards independent participants in downstream markets may decrease. This suggests that competition analysis should look beyond the effects of horizontal competition on consumers or total welfare towards to include the influence of value chain design on the generation and distribu-

352 Walles Ch. The rise of platform business – How digital networks are changing competition. 2018. <http://www.aprison.com/blog/2018/08/the-rise-of-platform-business-how-digital-networks-are-changing-competition/>

353 Strategic Policy Forum on Digital Entrepreneurship. https://ec.europa.eu/growth/industry/policy/digital-transformation/big-data-digital-platforms_da. The forecast uses as an assumption that most European companies use digital resources at the level that their competitors on the digital frontier already use. Increasing the share of value added comprises new transactions generated by the platforms, replacement of the less efficient instruments of advertising, planning, logistics by more efficient ones, and the development of new products and services that would be available by digitalization (for instance, within the area of the Internet of Things).

354 The extensive literature on the impact of MSPs on downstream markets does not fully support the expectations of anticompetitive influence on downstream markets. On the one hand, (Schmalensee, R. (1981). Monopolistic Two-Part Pricing Arrangements, *Bell Journal of Economics*, 11, 445; Whinston, M.D. (1990). Tying, Foreclosure, and Exclusion. *American Economic Review*, 80 (4), 837-859) have examined entry in complementary markets, but without focusing particularly on platform dynamics or cross-platform effects. These authors suggest that monopolists have several strong incentives for entering complementary markets to offer bundling or tying. On the other hand, other papers (Farrell, J. and M. Katz (2000). Innovation, Rent Extraction, and Integration in Systems Markets. *Journal of Industrial Economics*, 48, 413-432; Becchetti, L. and L. Paganetto (2001). The Determinants of Suboptimal Technological Development in the System Company-Component Producers Relationship. *International Journal of Industrial Organization*, 19(9), 1407-1421) show that if a monopolist cannot duplicate the entrants' innovations at a reasonable cost, then it may have strong incentives to try to state to entrants that it will not enter the market for complements to stimulate the competitive efforts of independent suppliers of the complementary product.

355 Gereffi, G., Humphrey, J., & Sturgeon, T. (2005). The governance of global value chains. *Review of International Political Economy*, 12(1), 78-104.

tion of value³⁵⁶. In the latter dimension, one important issue is vertical competition as a possibility of the participants in the chain to upgrade and receive a fair part of the overall amount of value generated.

In many dimensions, conditions for successful business models in MSPs are different from related conditions in markets where network externalities are weak. The same is true for conditions that profit-maximizing decisions should satisfy. As a result, standards to identify anticompetitive conduct that a competition authority traditionally applies to one-sided markets (occasionally with important reservations) could be inapplicable for MSPs.

Recall the example of below-cost pricing. We already know that “horizontal” dynamic economies of scale can lead to non-predatory below-cost pricing. However, with MSPs, there is an additional issue: network effects between different sides of the platform (“across the platform”) so that one can have below cost pricing on at least one of the sides where demand is more elastic. Such below cost prices do not reflect a predatory intent but they can have a predatory effect on firms which are not as “vertically” integrated” as the MSPs.

MSPs have the ability to unilaterally influence downstream markets, including pricing, product differentiation, and entry conditions. The influence of MSPs on horizontal and adjacent markets might also be anticompetitive. Antitrust enforcers worldwide focus closely on large MSPs, from Microsoft to Google³⁵⁷. However, in all these cases, the competitive analysis of MSP conduct³⁵⁸ can be tricky, for two main reasons. Firstly, even if some conduct reduces horizontal competition in a given market, cross-platform effects can generate compensating benefits in another market. Secondly, dynamic efficiency, which is central to many MSPs’ business model further complicate the task³⁵⁹. Therefore, a necessary step of the analysis is to weigh losses from competition restrictions against welfare gains. This is especially important under the analysis of economic concentrations.

Competition authorities in BRICS countries face the same problems when investigating and deciding on the conduct of MSPs as their colleagues do in more developed jurisdictions. In recent years, they have made important decisions on abusive conduct of MSPs

356 See more information on global value chain approach in: Lianos I. (2006). Global Governance of Antitrust and the Need for a BRICS Joint Research Platform in Competition Law and Policy. CLES Research Paper Series, 5/2016

357 See, for example, Evans, D.S. and Noel, M.D. (2008). The analysis of mergers that involve multisided platform businesses. *Journal of Competition Law and Economics*, 4(3), 663-695; Haucap, J., Stuhmeier, T. (2015). Competition and Antitrust in Internet Markets. DICE Discussion Paper, No 199; Market power of platforms and networks. 2016. Bundeskartellamt working paper.

358 The best-known example is a dispute between different interpretations of Microsoft conduct when crowding Netscape out of the market for web browsers. See: Gilbert, R. J., & Katz, M. L. (2001). An economist’s guide to *US v. Microsoft*. *Journal of Economic Perspectives*, 15(2), 25-44; Klein, B. (2001). The Microsoft case: what can a dominant firm do to defend its market position? *Journal of Economic Perspectives*, 15(2), 45-62; Whinston, M. D. (2001). Exclusivity and tying in *US v. Microsoft*: what we know, and don’t know. *Journal of Economic Perspectives*, 15(2), 63-80. In the discussion, many arguments were developed in the ‘one-sided market’ logic but at least taking into account direct network externalities.

and on remedies required for the approval of economic concentrations. The decisions of BRICS competition authorities have less extensively analysed than their counterparts in the EU or the US. This is especially unfortunate as BRICS policy towards digital MSPs might substantially diverge from that in the USA and Europe.

Important differences indeed arise because of BRICS' desire to catch-up with more advanced economies. In most BRICS countries, initial steps in the development of domestic digital markets were made by global rather than domestic platforms. At the same time, countries explicitly stress the strategic objective to develop national digital innovation systems³⁶⁰ involving domestic suppliers of digital solutions, including applications and business models.

The influence of market demand in BRICS on the potential competition in digital value chains, governed by MSPs, is contradictory. On the one hand, large market volume in many cases allows for interplatform competition, even if a platform exhibits substantial increasing returns to scale³⁶¹. At the same time, large market volume makes a domestic market attractive for global platforms, which then tend to dominate the local market. Therefore, domestic competition authorities may give special attention to the threat of foreclosure for domestic competitors and other forms of softening competition in favour of global MSPs, assigning higher weight to the gains of domestic competitors in developing theories of harm. In contrast, they may not take into account decreasing incentives of global companies to innovate as a negative externality of competition enforcement since the impact of their decisions on the investment policies of large global firms is likely to be minimal. Given this difference of perspective as well as the fact that mature jurisdictions have not elaborated a unanimous approach to competition policy, the BRICS need to develop their own approach towards MSPs.

The goal of this section is to describe and explain the approaches that BRICS competition authorities have taken so far towards MSPs. In the next sub-section, we briefly recall the theory of entry and exclusion under network effects. The following one summarizes implications from competition law and the economics of MSPs for enforcement, taking into account specific BRICS conditions. The final sub-section of this part reviews theories of harm/ competition concerns that BRICS authorities elaborate under enforcement, respective remedies and other instruments of competition policy.

360 See detailed description in the previous section.

361 UnionPay payment system is a successful newcomer in the payment system markets with large cross-platform effects due to large scale; Russian MIR ('World') is trying to achieve the same. In the Chinese market, there is intense competition between Alibaba and Tencent in many markets connected by relevant MPSS. In the Moscow market of taxi aggregator services, there has recently been sharp competition between Yandex-Uber, Sitimobil (domestic company) and Gett, with substantial changes in market shares annually.

2.1.2. Implications of the economic theory of MSP for competition policy

2.1.2.1. Incentives to enter and market structure of MSP

Competition policy addresses markets where demand and supply conditions make imperfect competition sustainable. A difficult task in these markets is to distinguish between market power that is explained by demand and supply and the conduct of dominant companies that enhance market power. In other words, competition authorities should distinguish between dominance and exclusionary abuse of dominance.

In the presence of MSPs, this task is especially difficult, as the economic theory of entry in the market with network effects shows. Conclusions of many models of network externalities apply to cross-platform network effects, especially models that involve the heterogeneity of customers. Moreover, certain models that were originally conceived for ordinary network externalities explain exactly the practices of MSP.

The economic theory of entry deterrence for a one-sided market followed several important stages. The starting point was that under high entry costs, entry deterrence could be achievable and profitable³⁶²: by choosing a price at which the entrant could not expect to cover the costs of entry, the incumbent could remain a monopolist. This theory of entry deterrence was criticized for the assumption (called the Sylos-Labini postulate³⁶³) that a potential entrant considers price (or quantity) set by the incumbent before entry as being unchanged after entry. If this assumption is not true, then pre-entry price (quantity) cannot predict the profit that a new entrant obtains in case of entry³⁶⁴.

If entrant and incumbent offer identical products, then they sell at the same price. In this case, production efficiency (cost advantage) of the entrant incentivizes entry, while entry costs disincentivize entry. If there is no cost of entry and the entrant has a cost advantage, entry always takes place in equilibrium. Similarly, the incumbent cannot sell the good at a price that substantially exceeds costs without the threat of entry unless entry costs are very high and/or the incumbent undertakes specific exclusionary actions.

However, these conclusions no longer holding markets with network effects. Consider³⁶⁵ a market for a network good with two sellers – incumbent (I) with the installed base (measured by the number of users N) and entrant (E) with zero installed base. The unit cost of the entrant is lower than that of incumbent $c_E < c_I$, and the entry cost of incumbent is zero.

362 See Bain, J. S. (1956). *Barriers to new competition*. Cambridge, MA: Harvard University Press.

363 Sylos Labini, P. (1957). *Oligopolio e Progresso Tecnico*, Milan: Giuffr ; English version: *Oligopoly and Technical Progress*, 1962.

364 Historically, this point was raised by Dixit (Dixit, A. (1980). The role of investment in entry-deterrence. *The Economic Journal*, 90(357), 95-106.) in the dispute with Spence (Spence, A. M. (1977). Entry, capacity, investment and oligopolistic pricing. *The Bell Journal of Economics*, 534-544).

365 The example presented further is based on Karlinger, L., & Motta, M. (2012). Exclusionary pricing when scale matters. *The Journal of Industrial Economics*, 60(1), 75-103. In the model, there is only one network good sold by an incumbent, and that good potentially could be sold by an entrant. However, for the overall logic, only network externalities matter for the conclusion.

Consider highly dispersed users with unit demand and willingness to pay, $P_i = f(N)$, $\frac{\partial f}{\partial N} > 0$; $f(N = 1) = 0$; $\lim_{N \rightarrow \infty} \frac{\partial f}{\partial N} = 0$. There are N old users who constitute the installed base of an incumbent, and they do not need to pay again for the good in a new period. Now, N new users appear in the market. As mentioned, the entrant has unit costs c_E which are lower than the unit costs c_I of the incumbent. Further assume that if the incumbent is unable to discriminate between old and new users, there are two pure-strategy Nash-equilibria. One is an entry equilibrium where the entrant sells at price $P = c_I - \varepsilon$, incumbent sets price equal to unit cost, and all users buy from the entrant. Another is an exclusionary equilibrium when incumbent sells at price $P = f(2N)$, entrant sets any price lower than incumbent, but all users buy from the incumbent. It follows that entry by a more efficient firm might be deterred even with zero entry cost and even though the incumbent charges the highest possible price. A customer does not gain from switching to a lower-price alternative if the positive network effect is sufficiently large. Indeed, if the available network for entrant is small ($F(2N) - F(N) > c_I$), no cost advantage would be sufficient for successful entry.

An incumbent with a large enough installed base does not need to sacrifice any margin to prevent the entry of a potential competitor. The model explains why size itself may prevent entry and may weaken competition, even without any intention or special actions from the incumbent³⁶⁶. A monopoly structure of markets with large network externalities may result from the cross-platform effect itself³⁶⁷.

This model has several implications for competition policy. The network effect is sufficient to explain the persistence of imperfect competition. Additional factors of cost and service advantages of a platform, including cost subadditivity, informational advantages because of data collected, or superior prediction abilities, are not necessary to explain high concentration. This basic difference should be taken into account by competition enforcement, possibly justifying a specific approach.

2.1.2.2. Impact of network externalities on the effectiveness of exclusionary contracts

For many platform businesses, participants on either side can choose between single- or multihoming. Single-homing might be economically justified without any special contract terms or might result from contractual clauses proposed by MSPs, explicitly requiring single-homing or making it de facto preferable by providing steep quantity or loyalty discounts. In the latter case, the effects of single-homing should be analysed through the lens of the theory of vertical restraints.

366 The important part of the model is the explanation of the impact of different degrees of price discrimination on the availability of exclusionary/ entry equilibrium. The authors show that under third- and second-degree price discrimination, only an exclusionary equilibrium is sustainable.

367 It is interesting to mention the parallels between this model and the model of sustainable natural monopolies (Panzar, J. C., & Willig, R. D. (1977). Free entry and the sustainability of natural monopoly. *The Bell Journal of Economics*, 1-22.). Under some circumstances, the possibility of free undeterred entry does not affect market structure or competition.

Historically, the so-called Chicago school provided important challenges to all the theories of exclusionary conduct under rational decisions of users and incumbents. A conventional presentation of the Chicago paradox³⁶⁸ is that if after entry an incumbent and an entrant with identical unit costs compete à la Bertrand (with equilibrium prices therefore equal to marginal costs), any exclusionary contract under a price higher than marginal cost cannot be supported in a Nash equilibrium. Because consumer losses from a price higher than marginal costs generally exceed the profit of the incumbent, the incumbent is not able to offer a bribe to consumers which is large enough to compensate them from the higher price that an exclusivity agreement would entail.

There is a wide range of post-Chicago models of vertical restraints, which identify conditions that make equilibrium with exclusionary contracts possible. The models include incomplete information on the cost function of a potential entrant³⁶⁹, imperfect competition after entry and specifically important for MSPs – miscoordination between users³⁷⁰. In particular, when entry deterrence requires exclusivity obligations from only part of the overall number of users, then the profits of the incumbent can suffice to bribe this subset of consumers into accepting an exclusivity clause so that an exclusionary Nash equilibrium exists.

The incentives and ability of MSPs to impose exclusivity clauses is greater than for single sided businesses.³⁷¹ Firstly, when a platform binds the users on one side (call it side B) with an exclusionary agreement, positive cross-platform (indirect) network externalities increase demand and willingness to pay on another side (call it side A). This makes it easier to compensate users on side B to prevent their profitable deviation from the exclusionary contract. As Armstrong and Wright stress³⁷², exclusivity in this case substantially affects the distribution of surplus across subgroups of users on either side because, under multihoming, MSPs compete for the users who are multi-homers, extracting the surplus from those who are single-homers. Competition forces lower prices for multi-homers (as their demand becomes more elastic – due to the Rochet-Tirole condition), but higher prices for single-homers.

Several remarks are important here. First, the redistribution of surplus between different sides of platform does not provide clear-cut criteria to identify a competition-weakening effect as the pattern is similar to the rule for pure short-term profit maximization – increase the price-cost margin for the side with low demand elasticity and ‘subsidize’ the side with high elasticity of demand. Second, exclusivity, or single homing, is not necessarily welfare-decreasing.

368 As presented, among others, in: Rasmusen, E. B., Ramseyer, J. M., & Wiley Jr, J. S. (1991). Naked exclusion. *The American Economic Review*, 1137-1145.

369 Aghion, P., & Bolton, P. (1987). Contracts as a Barrier to Entry. *The American Economic Review*, 388-401.

370 Rasmusen, E. B. et al., see footnote 22.

371 Amelio, A., Karlinger, L., & Valletti, T. (2018). Exclusionary practices and two-sided platforms. *Rethinking Antitrust Tools for Multi-Sided Platforms*, 131.

372 Armstrong, M., & Wright, J. (2007). Two-sided markets, competitive bottlenecks and exclusive contracts. *Economic Theory*, 32(2), 353-380.

It might be welfare-enhancing (and competition-preserving) when several competing platforms apply single-homing³⁷³. This is because the platforms' incentives to compete intensely to attract single-homers are high. Third, multihoming vs single-homing affects the welfare effects of other business practices.

Overall, then, the literature does not support any presumptions on the impact of exclusivity on competition and welfare. Particular business practices require specific analysis. At the same time, the effects of exclusivity and single-homing need to be considered not only under the enforcement of antitrust law but also in the context of the merger approval process. Merging one side of a platform in particular circumstances might be an easier means of achieving single-homing. Especially such incentives may arise in vertical mergers since its participants do not need to provide single-homing through exclusive contracts in order to increase the size of network.

2.1.2.3. Justifications of exclusionary conduct

The origin of the positive cross-platform effect is important to develop an efficiency defence for seemingly anticompetitive conduct. Theory and empirical evidence³⁷⁴ support pro-competitive justification for vertical restraints resulting in exclusivity when the sector is sufficiently competitive. To be competitive, a smaller platform might use vertical restraints to achieve critical mass and "get the ball rolling". In contrast, the efficiency defence for vertical restraints or similar policies of a dominant platform should address the origin of cross-platform effects. For transaction platforms, such as hotel booking platforms for example, the exclusivity clause might be the cheapest means of avoiding free-riding, in which parties use the information and contacts available through one platform before completing the transaction either on another platform or by contacting the other side directly.

For digital platforms, additional justifications arise because of the Schumpeterian nature of competition in the sector. In digital markets, competition often takes the form of envelopment³⁷⁵, also known as drastic innovation, in which a new technology completely crowds out the previous one. In such cases, the meaningful competition is *for* the market rather than *in* the market. In such a sector, the current structure of a platform market is not informative for an assessment of competition, just as in contestable markets³⁷⁶. What matters is whether dominance today or some of the actions enabled by today's dominance makes it more likely that the same company will remain dominant through several innovation cycles. For example, current dominance would not be a con

cern per se but the systematic acquisition of companies with potentially drastic innovations would be.

2.1.2.4. Unresolved and problematic issues in competition policy towards MSPs

A brief survey of economic models highlights several groups of implications for competition policy, including content of analysis, analytical tools and policy instruments. We begin with the type of analysis that competition authorities should undertake. Firstly, the effects of a particular conduct by a MSP depend on market structure and shares on all sides of the platform. Moreover, the same conduct (e.g., single-homing) may be pro-competitive for smaller platforms but anticompetitive for the dominant one. Therefore an effect-based approach should be applied towards digital MSPs³⁷⁷.

Secondly, it is difficult to distinguish between the deterrence effect of cross-platform network externalities and the effects of exclusionary conditions in MSPs' contracts. If the latter takes place, it can have significant welfare losses, both static (higher price level) and dynamic (worsening entry conditions and therefore a decrease of incentives to innovate by entrant).

Finally, in the competition jurisdictions where legislation addresses not only exclusionary but also exploitative abuses, sustainable dominance of an MSP makes exploitation of users possible. In terms of value chain theory (VCT hereafter), MSPs dominate over their respective value chains³⁷⁸, elaborating and enforcing rules of transactions between users on different sides of platforms.

Performing important tasks within the value chain, an MSP might be interested in re-distribution of the value created within the chain and even in preventing the upgrading of value chain participants³⁷⁹. There is not always a clear borderline between efficient value chain governance and what competition law calls exploitative abuses. This specific nature of the MSPs' position towards value chain allows for many theories of harm.

A second group of implications concerns the analytical tools available to the competition authorities. The bad news is the low discriminatory power of the tests, which authorities usually apply to 'normal' markets. If applied naively to MSPs, these tests would result in either a high probability of wrongful convictions (Type I errors) or wrongful acquittals (Type II errors).

As we have mentioned above, below-cost pricing on one side of a platform cannot indicate predatory intent. Correspondingly, cost-based tests on for excessive pricing on one side of a platform also lose discriminatory power, as a high price on one side of the plat-

378 Boudreau, K. J., & Hagiu, A. (2009). Platform rules: Multi-sided platforms as regulators. *Platforms, markets and innovation*, 1, 163-191.

379 Muzellec, L., Ronteau, S., & Lambkin, M. (2015). Two-sided Internet platforms: A business model lifecycle perspective. *Industrial Marketing Management*, 45, 139-150; Gawer, A. (Ed.). (2011). *Platforms, markets and innovation*. Edward Elgar Publishing; Gawer, A., & Cusumano, M. A. (2014). Industry platforms and ecosystem innovation. *Journal of Product Innovation Management*, 31(3), 417-433.

form might be the necessary compensation for low or even negative prices on another side³⁸⁰. The same can be true for other types of exploitative conduct. Taking into account the fact that profit-maximizing vector of prices for the clients of platforms implies a kind of 'cross-subsidization', any benchmarking analysis is extremely difficult, if possible.

Other traditional competition policy instruments and techniques might also be more difficult to apply. For example, the notion of 'Profit sacrifice' or 'no economic sense' tests cannot be applied to a single side of the MSP or even to a limited subset of the sides in which the MSPs are involved. Applying the test to a single side would risk concluding that there is a profit sacrifice even though the lower margins on that side help to generate higher margins on another side, without any profit sacrifice overall. An 'equally efficient test' for any exclusionary agreements is also difficult to apply for MSPs. Since the main source of efficiency is size as a driver of network externalities, an 'equally efficient' competitor should be a competitor of equal size of network. Even a mental experiment of that kind is extremely difficult to conduct as network benefits can be hard to value. The dynamic nature of platform markets add to the difficulties faced by competition authorities. On the one hand, large share does not automatically equate with dominance in terms of an ability to influence the market unilaterally³⁸¹. On the other hand, if vertical restraints prevent entry, this situation may induce substantial welfare losses in dynamic markets. With potential drastic innovation, dominance might be short-lived. However, the main MSPs have been there for quite a few years now. The possibility of drastic innovation does not imply lack of dominance in terms of unilateral static effect. It only does if the probability of drastic innovation itself increases when the MSP follow a particular conduct (say raise prices).

For exploitative abuses, additional complications arise when the competition authority selects a benchmark for comparison. One of the implications of VCT is that a dominant MSP may impose 'unfair' contract terms. However, standards of fairness are very difficult to follow anyway³⁸². Difference between MSP and traditional business model brings additional complications. Straightforward comparisons might be misleading. Taxi drivers under an MSP business model obtain substantially lower earnings per hour than do comparable taxi drivers in traditional taxi companies. *Uber, Gett or Yandex Taxi* for instance internalize transaction costs for both types of users – passengers and taxi drivers. In this respect, taxi services provided by an MSP differ from those provided by independent drivers. The same is true for drivers. As a result, comparison between per hour earnings would be possible only by taking transaction costs into account, which is extremely difficult. Return on capital would also be compared with great caution: under MSP business model risk both of aggregators and taxi drivers differs from the risk level of traditional taxi services, usually compared with. These complications are not particu-

380 Katsoulacos, Y., & Jenny, F. (Eds.). (2018). *Excessive Pricing and Competition Law Enforcement*. Springer.

381 There are many examples in platform businesses in which a seemingly dominant company was crowded out of the market due to drastic technological innovation (see Eisenmann et al, see footnote 29).

382 See, for instance, on the issue of fairness under European enforcement against excessive pricing: Jenny, F. (2018). Abuse of dominance by firms charging excessive or unfair prices: An assessment. In *Excessive pricing and competition law enforcement* (pp. 5-70). Springer, Cham.

larly specific to MSP, but they require sophisticated comparison of risks, returns, prices etc.

Unfortunately, the difficulty in supporting a theory of harm for MSPs does not mean that particular MSPs never adopt anticompetitive conduct, as the efficiency explanation of large size suggests. On the contrary, MSPs from Microsoft to Google have extensive records of exclusionary conduct³⁸³.

Sufficient evidence on the absence of anticompetitive conduct of an MSP on interplatform competition is an absence of any restrictions on multihoming, naked or constructive. However, regardless of the business practice of the MSP, such evidence is valid only in cases where multihoming is technically available, economically reasonable and is not hampered by behavioral biases on the part of users: if multihoming is possible, it also prevents exploitative abuses. If several taxi aggregator services compete, they compete not only for final customers but also for drivers. The probability of keeping drivers' compensation at a fair level increases under competition.

A third group of implications addresses the appropriate instruments of competition policy towards MSPs. If competition law and economics cannot provide a reliable set of tests to distinguish between lawful and unlawful conduct, the two remaining extreme options are nonintervention and sector-specific regulation. Sector-specific regulation for MSPs may emerge outside competition policy. For instance, there was a recent discussion on data as an essential facility that platforms obtain³⁸⁴, with strong arguments both pro and con³⁸⁵. International experience shows that the issues of market power over data might be addressed in different ways, including FRAND rules, widely applicable in the EU³⁸⁶, or by establishing explicit property rights on personal data, which would allow data portability³⁸⁷.

Advantages of the alternative solutions are that they do not rely on the premise that the assets of an MSP are essential facilities or that an MSP is a natural monopoly. In turn, this premise is not always easy to support. The boundary between 'natural monopoly'

and ‘contestable market of one seller’ is a threat of new entry or envelopment³⁸⁸. In some MSP markets, threat of new entry emerges because of quite similar use of applications. For instance, taxi aggregators and aggregators of food delivery work in similar way. In many markets that platforms use geolocations, entry on other market is possible and does not require high fixed costs. Envelopment may emerge in similar way, by developing of a particular digital decision for another purposes.

Unfortunately, the probability of envelopment often can be observed only *ex-post* but not *ex-ante*.

Limitations of the sector-specific regulation option follow from the dynamic and innovative nature of digital platforms. Many business practices still lack consistent assessment in terms of their impact on competition. Regulatory rules being fairly elaborated in procedural terms may not achieve desired objectives, but they can easily provide unexpected spillovers. One intermediate option for competition authority is to develop a code of fair business practice³⁸⁹. A code of fair conduct permits engaging a targeted protection group in the elaboration of rules and then combining a broad description of principles with industry expertise in conflict resolution.

2.1.3. Competition policy towards multisided markets in BRICS

2.1.3.1. Market definition and multisided markets

BRICS competition authorities usually apply different approaches to transaction vs non-transaction platforms. For transactions platforms (occasionally called aggregators – see, for instance, the decision on the *Uber-Yandex* merger)³⁹⁰, the affected markets are defined as platform services. However, the digital nature of a platform does not always serve as a feature that defines the market. For instance, in *Uber-Yandex* mergers³⁹¹, the Russian FAS considers ‘traditional aggregating taxi services’ to be a substitute for a mobile platform that belongs to the same markets.

The Brazilian CADE follows the same path in the assessment of the competitive effect of

388 See footnote 29.

389 In Russia, codes of fair conduct are developed in many industries where there are concerns, first, about exploitative conduct of dominant companies. Recently (Spring 2019), a code of fair practice for supplier-retailer contracting, a code of conduct for auto-makers and their dealers, and a code of fair practice in the pharmaceutical industry are in force.

390 Concept of aggregators vs platforms are widely explored in strategic management. A distinction is that participants in the value chain of aggregators do not contribute to the value that the aggregator provides. In contrast, a ‘genuine platform’ in its business benefits from the value created by the users. Therefore, for the aggregators, in contrast to platforms, there are no special incentives to invest in development of the users. Without disputing this distinction, even ‘pure aggregators’ such as online taxi services assist their users in promoting competitiveness. From the perspectives of competition law and economics, the distinction between aggregators and platforms seems to be not very important, even if is important for strategic management. In both cases, network effects explain market structure and efficiencies in the market.

391 Analytical Report on the Competition in the market of services of informational intermediation between taxi drivers and taxi passengers (market of taxi aggregators) (in Russian) Web-address: <https://fas.gov.ru/documents/678673>

Uber` s entry into Brazilian municipal markets. Independent taxi services are considered competitors in the same markets, affected by *Uber`* s entry. In both the Russian and Brazilian cases, a transaction between users defines the market.

In the case of nontransaction platforms (e.g. Facebook, Google), authorities generally consider several distinct markets, interrelated within the platform. For instance, in the case of distorted search results, the Competition Commission of India defines two markets: Online General Web Search in India and Web Search Advertising Services in India³⁹². Considering the alleged restrictions on *multihoming in sponsored search market*, CADE (2013)³⁹³ also does not include the other side of the platform in the market. In the *Android* case (2015), the Russian FAS considered that *Google* was dominant in the markets for *Operating Systems* market, in the *Application Store market*³⁹⁴, and the affected adjacent markets *pre-installation of applications, products, services*, where OEMs are buyers and application developers are sellers³⁹⁵.

2.1.3.2. Theories of harm

2.1.3.2.1. Exclusionary conduct through vertical foreclosure

Vertical foreclosure is at the center of the theories of harm in the investigations of MSPs. Some business practices might be considered *naked exclusion of competing services* (*Google Android Russia, 2015*) or foreclosure through the limitation on contract terms to other potential counterparties through price-parity conditions.

2.1.3.2.2. Exclusionary conduct through other forms of competition softening

Discrimination is another means of competition softening involving MSPs (see *Google Search* case, India, 2012). Discrimination in terms of access to customers' attention, 'clicks' and traffic substantially affects the competitiveness of products. To our knowledge, no decision of a BRICS competition authority contains a quantitative assessment of the impact of search distortion on the comparable competitiveness of suppliers towards final customers similar to the analysis performed by the Directorate General of the European Commission³⁹⁶. However, the underlying logic of the decision is essentially

392 Case No. 07 and 30 of 2012. Competition Commission of India. 2012. Web-address: <https://www.cci.gov.in/sites/default/files/07%20&%20%2030%20of%202012.pdf>

394 Decision and remedy, Case No. AD/54066/15. FAS Russia. 2015. Web-address: <https://br.fas.gov.ru/ca/upravlenie-regulirovaniya-svyazi-i-informatsionnyh-tehnologiy/ad-54066-15/>

395 Under appeal of the FAS decision, Google tries to challenge market definition by defining market more broadly as the market for software. An attempt to define the market in this way was rejected by a commercial court. The judge mentions, among other points, that this type of market definition does not allow identifying the source of market power and disguises abuses of dominance.

396 Press release Antitrust: Commission fines Google €2.42 billion for abusing dominance as search engine by giving illegal advantage to own comparison shopping service. Web-address: http://europa.eu/rapid/press-release_IP-17-1784_

the same. Standard of legal conduct in this case is ‘net neutrality’; a search engine is considered an essential facility that should bear specific responsibility to provide fair contract terms to competitors³⁹⁷.

2.1.3.2.3. Exploitative conduct in a value chain perspective

No competition authority of a BRICS country has issued a decision on pure exploitative conduct by a digital platform similar to the decision of *Bundeskartellamt* on Facebook³⁹⁸, where unfairness of contract terms with the final customer is sufficient condition for illegality.

From a value chain perspective, theories of harm applied to competition violations and to merger approval correspond can be ‘exploitative’ in the sense that (i) restrictions of competition prevent upgrading of the participants along the same value chain, and (ii) upgrading of the participants in the adjacent markets can be expropriated by the platform. The effect of expropriation (redistribution) of rent is articulated in the value chain perspective. If counterparties increase efficiency and reduce cost, the governing party decreases the compensation without passthrough to the final customers. One can use dominance at one or more stages of the vertical chain to expropriate the surplus of others in other stages and this reduces/eliminates these targeted firms’ incentives to innovate.³⁹⁹ To our knowledge, no competition authority explicitly includes this theory of harm as central in its decision. In the decisions on *Google Android* (2015), the Russian competition authority mentions potential losses of application developers that receive lower fees that they could when competition in the application stores market takes place.

Generally, if competition law and economics apply the value chain theory instead of the (mostly) neoclassical notion of market dominance, a relevant exploitative theory of harm would be either prevention of upgrading or unfair redistribution of rent⁴⁰⁰.

‘Vertical fairness’ in this context means contract terms that do not prevent upgrading of the participants of adjacent markets by expropriation of rents that parties may obtain for superior productivity. Different theories acknowledge the possibility of the gains obtained by cost reduction of quality improving to be expropriated. The theory of incomplete contracts develops a framework of relationship-specific investments and appro-

400 Davis, D., Kaplinsky, R., & Morris, M. (2018). Rents, power and governance in global value chains. *Journal of World-Systems Research*, 24(1), 43-71.

priable quasi-rent⁴⁰¹. There is however an important obstacle to building the theory of harm using an incomplete contract framework. Hold-up theory predicts that a rational independent agent would not be willing to invest in relationship-specific assets under the threat of hold-up. In the incomplete contract theory, the underinvestment problem is resolved by vertical integration or FRAND commitments, and vertical integration resolves the problem of rent expropriation. In the context of dominant platform businesses, participants in adjacent markets might be locked into the contractual relationship so that their rents are appropriated by platforms. However, in a pure framework of incomplete contracts, it would be difficult to explain how the lock-in emerges, if a rational counterparty does not invest or invests insufficiently under the threat of hold-up. Normative analysis shows the impact of potential hold up on the investment to upgrading but it would be extremely difficult to find a positive evidence in favor of the hypothesis on the negative impact of potential hold up on competition.

Generally, discussing this issue is avoided in the modern literature on global value chains. Providing extensive evidence of financialization⁴⁰², that is, appropriation of the cost reduction and quality improvement of the subordinated firms in the value chain by the lead one, authors do not provide an explanation of the efforts and investments of the first group.

This notion of exploitation differs from exclusionary theories of harm that competition enforcement applies even in very pro-regulatory regimes such as Russia. It is not yet a part of a notion of exploitative antitrust violations. The closest is *low monopolistic price* in Russian competition law, where *low monopolistic price* is the contract price paid by dominant buyer. There are no instances of the application of *low monopolistic price* towards MSPs. Similarly, decisions do not apply the notion of abuse of economic dependence⁴⁰³.

401 See Klein, B., Crawford, R. G., & Alchian, A. A. (1978). Vertical integration, appropriable rents, and the competitive contracting process. *The Journal of Law and Economics*, 21(2), 297-326. An interesting parallel between the theory of appropriable quasi-rent and definition of platform in strategic management (see footnote 43 above) is the notion of cooperative relation-specific investments (Che, Y. K., & Hausch, D. B. (1999). Cooperative investments and the value of contracting. *American Economic Review*, 89 (1), 125-147.). Cooperative investments are those that, first, are relationship-specific, and, second, benefit the partner of the investor but not investor himself. This benefit is exactly the effect of the investments of the participants in a market adjacent to the platform if we distinguish between platform and aggregator.

402 See, for instance, Milberg, W. (2008). Shifting sources and uses of profits: Sustaining US financialization with global value chains. *Economy and Society*, 37(3), 420-451; Milberg, W., & Winkler, D. (2011). Economic and social upgrading in global production networks: Problems of theory and measurement. *International Labour Review*, 150(3-4), 341-365; Milberg, W. (2008). Outsourcing economics. In *Economic Representations* (pp. 72-88). Routledge.

403 Bougette, P., Budzinski, O., & Marty, F. (2018). Exploitative abuse and abuse of economic dependence: what can we learn from an Industrial Organization approach? Working Paper, Web-address: https://papers.ssrn.com/sol3/papers.cfm?abstract_id=3086714. For Russian competition law, the explanation of the absence of a specific notion of economic dependence is that the notion of market dominance in the practice of enforcement captures the idea of strong dependence. In some extreme cases, competition authorities define market boundaries as bilateral relationships: Avdasheva, S. (2016). Models of monopoly in the quarter-century development of Russian competition policy: Understanding competition analysis in the abuse of dominance investigations. In *Competition law enforcement in the BRICS and in developing countries* (pp. 239-262). Springer, Cham.

If we nevertheless would develop a theory of harm using some version of incomplete contract and/or global value chain framework, it seems to be necessary, first, to acknowledge the unequal bargaining power of the seemingly independent parties. The explanation of the incentives and instruments of abuse would then be directly borrowed from the global value chain concept. The lead firm is able to appropriate rents accumulated by subordinated parties until there is a better outside option. Recall that it is only the lead firm in contrast to a subordinated one that has outside options. Competing to be the better outside option that is the only one that is able to keep the rent, subordinated firms allow for the lead firm to appropriate the gains they create. In the neoclassic analogue of this framework, welfare losses are the losses of distributional efficiency due to increasing inequality in the economy.

If we start from this point, then the evidence of abuse would be a large passthrough of the investments of the participants in adjacent markets on the profits of the lead firm. Until now, no competition regimes, including interventionist ones, is ready to go that far. Even if we accept the point that the rent appropriation in particular circumstances is possible (in the world of incomplete contracts with imperfectly informed users of platforms), and the asymmetric pass-through is an indicator of exploitative abuse (in terms of competition economy), the issue of measurement and comparison of this pass-through is hardly resolved. A similar issue arises in the attempts to enforce against excessive pricing. In Europe, an excessive price includes the characteristics of ‘unfairness’. However, four decades of enforcement have not allowed elaborating the proper threshold of ‘fairness’. A pass-through of efficiency gains from investments is much more difficult to decide on. As for excessive pricing, there is no proper threshold for a ‘fair’ distribution of gains. Additionally, in contrast to the excessive pricing, the pass-through of efficiency gains is not directly observable.

2.1.3.3. Efficiencies and multisided markets

Antitrust decisions towards MSP in BRICS rarely contain explicit assessments of efficiencies. One formal reason is that presumed violations of MSPs are more often illegal *per se*. For instance, tying of pre-installed applications with restrictions of pre-installation of competing applications (*Google Android, Russia, 2015*) is illegal *per se*. Another limitation on efficiency analysis arises from the fact that national authorities, when analyzing welfare effects, concentrate only on domestic markets. Under the global presence of a digital MSP, efficiencies captured by a platform would be missing from the analysis.

Under antitrust enforcement, an exception is the analysis of Most-Favored Nation (MFN) clause as a device to prevent free-riding towards a platform by the hotels in the CADE investigation in *Booking/Expedia/Decolar (2018)*⁴⁰⁴. CADE mentions that the threat of free-riding may destroy the positive welfare effects of a business model that minimizes

404 Booking, Decolar, and Expedia reach Cease and Desist Agreement with CADE. Web-address: <http://en.cade.gov.br/press-releases/booking-decolar-and-expedia-reach-cease-and-desist-agreement-with-the-brazilian-administrative-council-for-economic-defense>

transaction costs for the customers; therefore, efficiencies follow from the transaction-cost minimization.

In turn, there are examples of effect assessment, including efficiencies, in the decisions on mergers and ex-post evaluation of entry. An example of the latter is the assessment of *UBER* entry in Brazilian municipal markets during 2014-2016⁴⁰⁵. Ex-post analysis, which becomes important under discussions on proposed regulations of the taxi applications market, was concentrated on two main effects: price (fares) and entry conditions (measured by the quantity supplied by competitors). Therefore, the CADE approach addresses both final customers (passengers) and the effects on competitors. For the latter, CADE poses the question of whether a platform crowds out 'traditional' transactions. Under the approval of the Yandex-Uber merger in Russia (2017), FAS discussed similar evidence on decreases of fare per kilometer and changes in the number of rides by independent taxi services.

2.1.3.4. Competition remedies

Remedies normally appear under merger approval. In some BRICS countries, especially Russia, remedies are also issued under infringement decisions.

2.1.3.4.1. Remedies promoting interplatform competition

A typical remedy promoting interplatform competition is the support of the right of users to multihome. This support was the most important remedy under the *Yandex-Uber* merger in Russia (2017). *Indian Competition Commission in 2012*, in the Shopping case, ordered Google not to apply restrictive clauses in its negotiated direct search intermediation agreements with Indian partners. Remedies are aimed not only at naked restrictions on multihoming but also at indirect restrictions. An example is the commitment decision of Brazilian CADE in the *Booking/Expedia/Decolar* (2018) case, where online travel agencies agreed to stop using a price-parity clause policy and renounce the conditions imposed on hotels that offer accommodations on their platforms.

Remedies for multihoming tend to protect competition between MSPs, which is horizontal competition. Nevertheless, they may also affect vertical competition by limiting the unilateral bargaining power of particular digital platforms in their relationships with participants in adjacent markets. From a value chain perspective, the protection of multihoming is very important, although not necessarily sufficient, to protect upgrading opportunities. In particular, in the investigation of *Booking/Expedia/Decolar*, CADE specifically stresses the adverse effect of MFN clauses on the abilities of other agencies to enter the market and the distribution of rents between hotels and online travel agencies.

405 CADE analyzes the competitive effects of the Uber's entry in the market, especially over taxi apps. Web-access: <http://en.cade.gov.br/cade-analyzes-the-competitive-effects-of-the-uber2019s-entry-in-the-market-especially-over-taxi-apps>

2.1.3.4.2. Remedies promoting intraplatform competition

In turn, remedies on fair access terms directly affect the bargaining position of platform users. They try to promote the ability of competing ‘unbundled’ sellers in adjacent markets to supply their services using the capacities of the platform. Typically, this type of remedy addresses the issue of discrimination towards competing market participants by MSPs. In the simplest version, this type of remedy is presented by the settlement decision of *Google* with Russian FAS (2016), in which Google voids the exclusionary clause of its Android applications and commits not to encourage OEMs to install only *Google* applications. Thus, competing sellers can take advantage of using *Android OS* under conditions that are typical to essential facilities that are subjects of specific access rules, being a *bottleneck* in the markets.

Remedies in the *Google* Search case in India (2012) address the ability of all noncaptive participants in adjacent markets to be presented in the search results in a search engine as a platform. The decision explicitly states, «... As Google has the ability and the incentive to abuse its dominant position, its “special responsibility” is critical in ensuring not only the fairness of the online web search and search advertising markets but also the fairness of all online markets, given that these are primarily accessed through search engines»⁴⁰⁶. Relevant remedial requirements should display a disclaimer on the commercial flight unit box that clearly states that the “search flights” link at the bottom leads to Google’s Flights page rather than the results aggregated by any other third-party service provider, so that users are not misled.

Clauses that directly promote intraplatform competition also appear in decisions on mergers. Such decisions may address many adjacent markets, even without a specific analysis of competition concerns. For example, MOFCOM in *Google-Motorola* merger (2012)⁴⁰⁷ specifies rather general conditions for business practice in China:

- maintain free Android open source licensing for 5 years;
- maintain nondiscriminatory access to its Android system for 5 years; and
- continue licensing Motorola Mobility patents on a fair, reasonable and nondiscriminatory (FRAND) basis.

Generally, remedies addressing intraplatform contracts directly support vertical but not horizontal competition. They concentrate on the objective of preserving competition in adjacent rather than platform markets.

2.1.3.4.3. Other remedies

Regulatory interventions that affect competition in the markets do not necessarily use

406 Case No. 07 and 30 of 2012. Competition Commission of India. 2012. Web-address: <https://www.cci.gov.in/sites/default/files/07%20&%20%2030%20of%202012.pdf>

407 Conditional Clearance of Google-Motorola Mobility Acquisition. MOFCOM. 2012. Web-address: <http://www.zhonglun.com/UpFile/File/201206121014294533.pdf>

traditional tools of competition policy within competition legislation. Restrictions for foreign-originated platforms due to the specific requirements for the collection and use of data have an important stimulating effect on domestic competing platforms. The development of *Baidu*, *AliBaba* and *Tencent* in China was supported by specific requirements for data protection and data sharing. The *China Operating System*, if successful, will be another example of an alternative approach to competition development in BRICS.

There is no consistent assessment of the economic effects of the Chinese model of competition protection. Recently, however, in the Chinese markets adjacent to digital platforms (such as advertising, online video, music, B2C and O2O commerce, mobile payment and logistic, etc.), there is competition between the platforms that necessarily benefits participants of these adjacent markets.

In Russia, a draft of the law that should affect vertical competition between platforms and adjacent markets outside the scope of traditional competition enforcement was issued at the beginning of 2019. The proposed changes to the Russian law 'On communications' require for all mobile devices imported into Russia, first, domestic applications (including antivirus, browser, messenger and geolocation) should be pre-installed; second, all pre-installed applications developed by foreign companies should be removable. The expected effect is the redistribution of rents created in the value chain of the digital platform towards domestic application developers. However, this type of requirements is much closer to competition remedies promoting intraplatform competition and a supporting model of independent development of domestic digital platforms.

2.1.4. Conclusion

In the last decade, BRICS competition authorities have obtained records on competition enforcement towards MSPs. Under enforcement of competition legislation, theories of harm in investigations and decisions are mostly of an exclusionary, not exploitative nature. Discrimination and tying are typical qualifications of anticompetitive conduct. Exclusionary effects constitute competition concerns under merger approval. Until recently, few contained quantitative assessments of effects – but such assessments do not differentiate substantially between BRICS competition decisions and decisions in mature jurisdictions.

No restriction on multihoming is a universal remedy under both investigations of infringements and merger notifications. Special attention to vertical restraints with exclusionary effects reflects post-Chicago law and economics concerns about incentives to restrict competition. In this respect, the approach of BRICS contradicts neither the economic theory of competition in platform markets nor the practice of developed countries. An important gap in the decisions is the efficiency defence; competition authorities rarely undertake this type of analysis. It seems that neither do companies under enforcement try to develop this line of defence. Decisions on MSPs in BRICS rarely use a specific economic theory of platform competition (if any do so at all). They mostly rely on the standard theory of competition.

The economic theory of platforms does not exclude exploitative theories of harm. However, BRICS competition authorities do not apply them. In some BRICS countries, specific regulatory requirements are designed to support inter- and intraplatform competition. Their impact on rivalry and efficiency recently is understudied.

2.2. Theories of harm for multi-sided platforms II: practical implications for BRICS competition policy

Eduardo Pontual Ribeiro & Svetlana Golovanova

Multi-sided platforms are ubiquitous business in many sectors, particularly in digital markets, taking advantage of the internet communications and information power. These multi-sided, often two-sided, platforms provide an opportunity for users of both sides to interact and solve, in many cases informational problems that hindered transactions. The two-sided markets are often characterized, from the demand side, by the presence of network externalities across sides of the platforms. In other words, the attractiveness of doing business with the platform on one side depends on the number of users of the other side and vice versa. This attractiveness is enhanced by the possibility to predict user behaviour on either side, generating earnings opportunities to the other side or the platform itself.

From a supply side perspective, multi-sided platforms share cost and technological characteristics of firms using information as input or output, namely, small marginal costs but large fixed costs, together with returns to scale (Shapiro and Varian, 1999)⁴⁰⁸. In addition, these platforms generally experience learning-by-doing cost dynamics, i.e., they can reduce the cost or improve the quality of their products as their cumulative output raises over time, with consequences for market structure as in Dasgupta and Stiglitz (1988)⁴⁰⁹.

The multi-sided platforms often introduce new business models for specific sectors, and/or improve their services and internal practices with constant product or process innovations. The innovation dimension suggests that dynamic competition characteristics are central. Where platforms operate may have important competition for the market as well as in the market.⁴¹⁰

These characteristics of multisided platform generate the need to adapt the tools of competition policy analysis, both for merger and for abuse of dominance control. The cross-network effects influence demand and pricing such that they require practitioners to adapt the relevant market delineation and inferences on market power, either by concentration measures or with price pressure indices in merger analysis. The network effects, pricing rules, cost structure and dynamics and the innovation based character-

408 Shapiro, C. and Varian, H. (1999) *Information Rules*, Harvard U Press.

410 For one discussion of these concepts, see Geroski, P. (2003). *Competition in Markets and Competition for Markets*. *Journal of Industry, Competition and Trade*, 3(3) 151-166.

istics of many of these platforms impose careful analysis in abuse of dominance cases, particularly price-cost comparisons.

We explore these issues, providing suggestions for authorities and practitioners and a perspective from BRICS countries. While discussions of antitrust tools can be found in important forums (e.g. OECD, 2018, CRESSE Meetings, EU, 2019⁴¹¹), we organize the material for both merger analysis and abuse of dominance cases in an integrated framework.

The paper is organized as following. The next section provides the basic dimensions and differences between two-sided or multi-sided platforms firms and markets and one sided markets for competition policy analysis. The literature converged to identifying different types of multi-sided markets. Recognizing the type of two-sided market helps clarifying how to delimit markets. The following section describes the adjustments in the hypothetical monopolist test implementation using Critical Loss Analysis as well as other tools for market delineation, given different types of two sided markets and the role of concentration for market power inference. The last section presents suggestions of tools for abuse of dominance tools, before concluding comments.

2.2.1. Issues to be resolved under antitrust analysis of MSPs

2.2.1.1. To decide whether the MSP concept is necessary

A central distinctive characteristic of MSP is the existence of cross-side positive/negative externalities related to the number of agents on the other side of the platform, the so called indirect network effect or cross-platform effect. The effect can be present in the case of any business that acts as an intermediary.

One key difference is that in two sided markets, contrary to regular intermediary business, both sides can be charged to access the platform. For the case of a supermarket, while it wants to carry a large variety of goods to attract consumers, it pays for the goods that are on display on its aisles. This is a regular, vertical intermediary business. On the other hand, if the supermarket sees itself as a place to generate interactions between product manufacturers and customers, so that it can actually charge producers to have their goods in the supermarket inventory (e.g. when a large portion of its profits come from shelf space auctions for product suppliers) it would then be considered a two sided market for competition policy, as noted by Pike (2018)⁴¹².

The main point is that the two-sided nature has to be relevant for the firm's business behaviour to be taken into account by competition authorities. Just like a competition authority must weigh the costs and benefits of its intervention in business practices that may generate price increases and hurt competition, the Authority must contemplate whether the two-sided characteristics are central to the firm's business plans to alter its

411 EU (2019), Competition Policy for the digital era: Final report. European Commission.

412 Pike, C. (2018) Introduction and Key Findings: In OECD, Rethinking Antitrust Tools for Multi-Sided Platforms. OECD.

common analytical tools. The key question is whether the cross-platform effect is the main determinant of the profit of the company that exploits it.

Once the relevance of the cross-platform effect on the business model is identified, important characteristics of the platform will influence market delineation and the competition policy analysis.

2.2.1.2. The need to identify the type of the MSP and approaches to market delineation

Economists distinguish between *transaction* and *non-transaction* multi-sided markets⁴¹³. The classification is very important for understanding economic effects of multi-sidedness and market delineation in case of MSP. In particular, one should address if in a two sided platform one should delimit one platform with consumers from both sides, or two interrelated markets, one on each side of the platform. A summary of MSP classifications for competition policy analysis is provided in Table 1.

Transaction markets are those at which transaction between different (usually, two) groups of platform users are observable. Uber taxi is a good example. In this case the product offered by a platform is the transaction that occurs through it. Different groups of users can be charged a per-transaction fee for using it (although two-part pricing that include a membership or joining fee is not ruled out). Uber charges per ride, not for membership, for example.

An important additional characteristic of the role of two sides in altering the analysis from the usual market analysis is whether the platform is able to control relative prices charged to the two sides. If the sides of the platform can interact and negotiate the incidence of the fees of the platform on one side, platform ability to exploit the two sided nature of the platform is lost as complete pass-through is possible. From this point of view multi-sidedness of the market gives no special tools to a platform, that desires to affect side A demand for its services by manipulating prices for side B users. With pass-through this manipulation is not possible and the market can be analysed as a single market where the price structure is not relevant to attract customers on either side to the platform's benefit. With pass-through the sides internalize their externalities and the cross-side network effect is not influenced by the price structure. Moreover, services provided by a platform to its users at different sides are perfect complements as 'transaction' means that the service to A-type user can be provided only in case some B-type user consumes its service at the same time.

Taking all this into account in two-sided transaction markets one should define only one market – the market of transaction services. Economic agents may use and pay for services of one of competing platforms (if any) or transact without intermediary. Unless the platform is able to restrict economic agents in their ability to choose how to transact with each other the price should reflect the value of the platform services (quick search

413 See Filistrucci, L. (2018) Market definition in multi-sided markets. In OECD, Rethinking Antitrust Tools for Multi-Sided Platforms. OECD, and papers therein

Table 1. A summary of MSP classifications for competition policy analysis

	Do sides transact through the platform? Are the transactions observable?	
	Yes	No
Market Type	Transaction markets	Non-transaction markets
	Do pass-through effect present?	Do both sides search for matching?
	No	Yes
	Transaction markets without pass-through	Transaction markets with pass-through
Network effects	Are network effects positive for all sides of the platform?	
	Yes	Yes
Markets to be determined	One multi-sided market. The product is ability to transact with another side of MSP	One multi-sided market. The product is ability to find matching
Pricing strategy	Relative price affects the market, so fees for different sides are to be charged separately	MSP cannot control relative prices, so it focuses on the total price (sum of prices charged for both sides)
Market characteristics	Market size is to be measured by value/ volume/ number of transactions Prices are different for different sides	Market size is to be measured by the number of users on both sides. Prices are different for different sides
Market delimitation	SSNIP for one market corrected for cross-platform effects	SSNIP for one market corrected for cross-platform effects
	Traditional SSNIP for one market	SSNIP for each of the markets corrected for cross-platform effects
	Market size is to be measured by value/ volume/ number of transactions Price of transaction is the sum of prices charged for both sides	Several markets with their prices and volumes. Network effects are to be taken into consideration, when estimating demand and evaluating rivalry and entry
	Relative price affects the market, so fees for different sides are to be charged separately	Only participation fee. In addition, if the "audience" side generates strong positive cross-platform effect, it is rational to minimize its participation fee or to provide it some matching service (it would be a separate multi-sided market). The side that searches for the audience is to be charged participation fee.
	Market size is to be measured by value/ volume/ number of transactions Prices are different for different sides	Several markets with their prices and volumes. Network effects are to be taken into consideration, when estimating demand and evaluating rivalry and entry
	SSNIP for one market corrected for cross-platform effects	SSNIP for each of the markets corrected for cross-platform effects

of the counteragent, better matching etc.) for the users. The total price charged to both sides should be counted as this is relevant for profitability. The prices may be different across sides depending which side is more responsive to prices and/or generate the more externalities for transactions.

Non-transaction markets are those at which different groups of platform users do not transact directly or the transactions are not observable. The most well-known example is 'audience providing' or 'advertising' platforms which provide one user group (advertisers) with the audience or attention of another user group (readers), as in Pike (2018)⁴¹⁴. Advertisers cannot tell whether its ad was actually viewed or the product announced was later purchased. In non-transaction markets pass-through is not possible and the platform has perfect control over the relative prices charged to different sides. The control becomes a source of extra benefits for the platform, as it internalizes the cross-network externalities.

In the case of non-transaction markets the intensity of cross-sides externalities determines if the multi-sided nature of the market should be taken into consideration in an antitrust investigation. In case the externalities are weak and there are no reasons to believe that they are taken into account in the price-setting strategies of the platform, the analysis should proceed as usual, delimiting two different markets in each side acting mostly independently, with no feedback effects. Otherwise, the two relevant markets on each side are deeply interrelated.

Inferring the effect of mergers or anticompetitive conducts on two sided platforms requires the evaluation of whether consumers use only one platform or use competing platforms at the same time. Wismer and Rasek (2018)⁴¹⁵ indicate that on the side where consumers single-home, there may be fierce competition to attract users. Yet if the other side multi-homes, the platform may use its single-homing customers to create local monopolies, and exploit its market power on the multi-homing side, suggesting little competition on this side. Thus inferring whether multi-homing is present or not in either side is important for evaluation market power. Consumer data and surveys are the suggested methods to infer the extent of multi-homing.

2.2.1.3. The need to identify and test abusive intent

In the case of MSP we can follow the same classification of types of abusive conducts used for traditional markets, such as exploitative abuses and exclusionary abuses.

Exploitative abuses (excessive / unfair price, price discrimination) are the most complex and controversial subjects of competition law. After decades of efforts no reliable enough criteria for the threshold that distinguishes 'fair' and 'unfair' prices of a dominant company is developed. In case of MSP the matter is not more transparent. That is why below we discuss exclusionary abuses only. It is worth mentioning however that all

414 See footnote 4.

415 Wismer, S., Rasek, A. (2018). Market definition in multi-sided markets. In OECD, Rethinking Antitrust Tools for Multi-Sided Platforms. OECD.

comments given below for specific technical problems related to the identification of predatory pricing (all types of price-cost tests) are relevant in case of excessive (unfair) price investigation.

Exclusionary abuses are business-practices aimed at driving competitors out of the market and strengthening the dominant position. The main types are:

Exclusive dealing. In case of MSP the practice takes the form of single-homing as a necessary condition for dealing with a platform or a condition for getting rebates. Keeping control over the 'bottleneck', MSP can use its dominant position and spread its market power to the other side of the market and interrelated markets as well.

Tying and bundling. MSP is often present at many transaction and non-transaction markets and have an opportunity to practice tying and multi-products rebates. The greater is the number of products in the bundle, the stronger is the anticompetitive foreclosure.

Predatory pricing. One-side price-cost comparison does not make sense in case of platforms. Given the cross-side network effects it may be rational for a firm, with no exclusionary intent, to price below marginal cost, so to attract more customers to the other, more profitable, side of the platform. Besides, pricing below cost might be the only way for a platform to reach the threshold in the number of users necessary to make the network attractive for users.

Margin squeeze may take place, for example, when a platform charges its competitors for access to its client databases at the level that makes their business unprofitable. For merchant platforms, a margin squeeze may be detected when the difference between the retail prices charged by a dominant undertaking and the wholesale prices it charges its competitors for comparable services is negative, or insufficient to cover the product-specific costs of the dominant operator for providing its own retail services on the downstream market.

In case of MSPs anticompetitive effects of the practices should be evaluated with more care as cross-side and network effects may worsen the anticompetitive effects or actually reflect the pro-competitive effects of these business practices.

As discussed in the introduction, supply side characteristics of multisided platforms, namely, economies of scale and learning by doing generate significant barriers to entry and possible avenues for exclusionary behaviour. The economies of scale arise from both the digital /software dimension, where serving an additional customer entails very low or not costs, with very high fixed costs of product or software development, information gathering and processing and brand recognition.

Many a platform central competitive leverage is the possibility of personalizing their supply either by providing the consumer a more personal experience or matching one side of the platform interests with other side of the platform profile⁴¹⁶. Economic relevant cost dimensions are associated with this prediction process. First, there may be significant data requirements for this prediction dimension of the platform, as signifi-

416 We thank Prof Lianos for comments on this perspective on the flip side of many matching business model platforms.

cant consumer data are needed to machine learning (forecasting model selection) of their prediction models. Entrants could be pressed to access similar amounts of data so to have the possibility to exert competitive pressure with a similar quality good. Second, the prediction platforms in particular, but many platforms that provide matching in general, experience significant learning-by-doing as their prediction models need experimentation to validation and improvements. Prediction models must be ‘trained’ and evaluated with actual transactions. While the level of such data as a barrier to entry has been recognized in the literature⁴¹⁷, the learning-by-doing dimension is less explored, but can have significant anticompetitive effects⁴¹⁸ as data access becomes a necessary but not sufficient competition remedies.

2.2.1.4. The need to choose tests for potential consumer harm in mergers and dynamic competition

When considering the risk of consumer harm from mergers, the analysis should follow the same dimensions in standard one-sided cases: mergers may reduce competition significantly, thus generating harm to consumers in both static and dynamic dimensions. In a static analysis the merger may give rise to unilateral price increases or generate coordinated effects. In a dynamic analysis the merger may reduce innovation, firm entry and/or product quality.

The risk of unilateral price increases can be inferred using a quantitative test, namely the (gross) upward pricing pressure (UPP) index (GUPPI). For coordinated effects the literature has not explored the adjustments necessary to the agreement, deviation, and punishment analysis for two sided markets. In this paper we shall discuss the GUPPI tool for unilateral effects after we discuss relevant market delineation.

Platforms, in general, are technology intensive. They use information and processing power to propose new business models. In this perspective the merger analysis of two sided platforms should consider Shumpeterian competition analysis, i.e., dynamic competition tools, as in Shapiro (2011)⁴¹⁹ or Sidak and Teece (2009)⁴²⁰. Evaluating barriers to entry becomes central in antitrust analysis, while market shares levels are not informative, e.g. Shelanski et al. (2018)⁴²¹. Standard dynamic analysis points that the evolution of market shares is informative of market power as firm’s dominant position may be quickly eroded by new, innovative firms that enter the market. For the case of two-sided market the limited informational content of static market shares is compounded by

the challenges to delimit markets and calculate market shares. More importantly the network effects may ‘tip’ the market from a firm to another in a short time (as the late examples of Orkut or Microsoft’s Messenger show)⁴²².

As recent developments in dynamic analysis, Federico, Langus and Valletti (2018)⁴²³ suggest that merger effects on innovation are negative, although there may be two competing effects. On the one hand, a merger internalizes price effects between firms, reducing competition between them and increasing the benefits of innovation. This would lead to mergers improving dynamic competition, by fostering innovation. On the other hand, the benefits from innovation by each of the firms are diluted by the innovation efforts of the other. They show that the second effect is stronger, leading to the conclusion that mergers do generate a loss of dynamic competition. Interestingly for this chapter, the authors indicate that the negative net incentives to innovation after a merger are more likely when firms innovations can potentially divert large sales from the other merging party (an innovation induced UPP diversion like effect) and when there are few other innovators in the market.

The innovation dimension can benefit from the learning-by-doing theory proposed by Dasgupta and Stiglitz (1988)⁴²⁴. In its simplest form the learning-by-doing indicates that innovation requires learning so dynamic competition depends on accumulating experience in producing a good or service. The authors point out that this has implications for market structure. When incumbents experience strong learning-by-doing opportunities, in the authors’ sense, concentration may arise as initial cost benefits accumulate over time by learning and generate advantages to these firms in plausible cases. With respect to entry, learning can justify firms to block entrants with predatory pricing as their future costs would decrease, guaranteeing the success of this strategy.

One important discussion when evaluating theories of harm are the allocation and consideration of potential efficiencies from mergers or business practices within each relevant market or across markets, in the case of non-transaction markets. This is a point of very heated debate, as shown in the recent US Supreme Court decision of American Express case (see, e.g., Hoverkamp, 2019)⁴²⁵. In the case of transaction markets, when one single two sided market is delimited, the issue becomes whether efficiencies on both sides should be weighed against possible anticompetitive effect on one side. In the case of non-transaction markets, when two separate markets are delimited, the issue is whether efficiencies in one market could compensate for anticompetitive effects the other market. While in general the practice is to consider efficiencies in specific mar-

422 The so called ‘death spiral’ effect is the twin side of the network effects. An informal discussion is here <https://digit.hbs.org/submission/the-rise-and-demise-of-groupon-the-importance-of-satisfying-both-sides-of-a-two-sided-network/> and see also Evans, D; Schmalensee, R (2010) “Failure to Launch: Critical Mass in Platform Businesses,” Review of Network Economics: Vol. 9 : Iss. 4, Article 1.

kets, Ducci (2015)⁴²⁶ argues from an European Competition Law perspective, that when platforms have consumers in either side, the consumer welfare standard of competition policy could rationalize the evaluation of out-of-market efficiencies. For the BRICS countries, this suggests a starting point of discussion of each country based on their competition law standards.

2.2.2. Delimiting markets and measuring market power in two-sided markets: the role of demand functions.

As mentioned above, measuring market power is central in any antitrust investigation. The usual procedure to such measurement starts with delimiting the relevant market. From the list of actual competitors for the purpose of the antitrust investigation, market power is inferred from market shares or/and concentration indices of that relevant market. The paradigm for delimiting a relevant market is the Hypothetical Monopolist Test, described in Horizontal merger guidelines in almost all jurisdictions. A known quantitative tool for delimiting a relevant market is the Critical Loss Analysis or CLA (other quantitative tools are available, as we shall see below).

In addition to market shares, particularly since the 2010 US Horizontal Merger Guidelines, there has been a trend to infer the abuse of market power likelihood in a merger using price pressure indices and other diversion ratios, such as GUPPI (Farrell and Shapiro, 2010⁴²⁷ and Salop and Moresi, 2010⁴²⁸).

Either in delimiting markets or inferring market power, demand estimates (jointly with assumptions on competitive behaviour) are central. Demand elasticities are used in critical loss type analysis or in measuring diversion ratios for GUPPI type indicators.

Demand estimation for markets with two-sided characteristics must take into account the cross-platform externalities across platform sides. From the two canonical models of market analysis for two sided markets described in Rochet and Tirole (2006)⁴²⁹, the cross network externalities may take the form of an interaction effect in the actual output or the form of an explicit complementarity across sides on the demand function.

In the first case, associated with transaction two-sided markets, the actual demand for transactions (Q) would be modelled as $Q = D_A(P_A) D_B(P_B)$ where $D_i(P_i)$ $i=A, B$ are the demand functions in each side of the platform. Here each demand depends on the price charged to each side. Even if zero prices are charged in one of the side the demand function should account for network effects. We consider for exposition a monopolist, so that a single price is relevant for the demand in each side. In markets with many producers the demand function should consider prices of all producers. In this model there are cross

network effects on the number of transactions, although the price demand function in each side does not incorporate the price (or quantity) or the other side.

In the second case, associated with two-sided membership markets, the demand function on each side would be characterized as $Q_A = D_A(P_B, Q_B)$ and $Q_B = D_B(P_A, Q_A)$, where $\partial Q_i / \partial Q_j \geq 0$, $i \neq j$, in general, although negative network effects are not ruled out by theory. Again, we consider a single firm price as relevant for each side for expositional purposes. This demand function system can be written as 'reduced form' in prices, as $Q_A = D_A(P_A, P_B)$ and $Q_B = D_B(P_A, P_B)$, where $\partial Q_i / \partial p_j < 0$, $i \neq j$, following the cross-quantity effect sign. On this reduced it is clear from the demand function the platform sides are complements. Transactions are not observed by the platform, so the network externality accrues to the quantity on each side of the market.

Actual estimation of these demand function face additional challenges compared to the usual demand estimation requirements for identification (such as the use of instrumental variables). Compatible data (in units, data sources, time periods, e.g.) from both sided of the markets are needed. Dealing with zero prices also implies adjustments, in the demand estimation of the zero price side, where other competitive dimension might be relevant; e.g. Jeziorski (2014)⁴³⁰.

There are few examples of demand estimation in the literature for the above demand functions. Most, if not all, deal with the second type of demand system, for non-transaction markets. They actually deal with non-digital markets such as printed media readership and advertising (newspapers in Italy in Argentesi and Filistrucchi, (2007); newspapers in the Netherlands in Filistrucchi et al. (2012a, 2010, 2012b); TV magazines in Germany in Song (2015))⁴³¹.

Both Argentesi and Filistrucchi (2007) and Song (2015) estimate demand models for each side of the market using the well-known (Nested) Logit demand functional form, expanded to include quantity measure from the other side. They estimate structural models of the $Q_i = D_i(P_i, Q_j)$ type. In Argentesi and Filistrucchi paper cross-platform effects are present in the advertising side only.

For Argentesi and Filistrucchi (2007) data suggests multi-homing is not a common practice for the majority of consumers on either side, so it is assumed single-homing is the norm. Instruments are other firms' product characteristics as common in Logit models.

In Filistrucchi et al. (2012a) the multi-homing issue on advertising is opposite, with advertisers 'all-homing'. In general the limited literature does not provide a special treatment of single-homing/ multi-homing, but for the adjustment that it multi-homing is possible the membership numbers can be larger than the number of users.

2.2.2.1. Critical Loss analysis, SSNIP and HM test

The most rigorous quantitative tool used for market delineation is the so-called "Small But Significant Non-Transitory Increase in Price" test (SSNIP test). It is aimed to define the smallest set of substitute products such that a substantial (usually 5-10%) and non-transitory (usually one year) price increase would be profitable for a hypothetical monopolist. If it is not profitable, then at least one close-enough substitute to the product is expected to exist.

The SSNIP test is often performed by Critical Loss Analysis (CLA), as mentioned by Davies and Garcés (2010)⁴³². The idea is to compare a "Critical Loss" in sales (the percentage loss in quantity of a product sold by a hypothetical monopolist which is enough to make an X percent price increase unprofitable) and "Actual Loss" in sales (the predicted percentage loss in quantity that the monopolist would suffer in case of price increase by X percent).

For regular one sided markets, the most used formulas for the:

Critical Loss (CL) is: $CL = X/(X + M)$. This would be compared to the Actual Loss (AL) from a SSNIP, that can be estimated. Actual Loss: $AL = X\epsilon^{HM}$

where M is the percentage markup, and ϵ^{HM} is the price elasticity of the hypothetical monopolist (collection of firms in the candidate market), respectively.

The model assumes that firms within the market do not optimize the price increase and that the criteria is whether the X SSNIP price increase is profitable or not (breakeven condition).

A relevant market is determined when $CL \geq AL$. If $CL < AL$, the SSNIP is not profitable suggesting that there are close enough substitutes outside the hypothetical group of firms within the relevant market. The market should be expanded to include more substitutes.

The formulae can be adjusted for a Critical Elasticity and Actual Elasticity, dividing both sides by a percentage price increase, i.e., the SSNIP, namely,:

Critical Elasticity: $\epsilon^{HM*} = 1/(X + M)$

If the (absolute value) of the actual hypothetical market price elasticity is larger than the (absolute value) of the critical elasticity, the candidate market should be enlarged.

In case of a multi-sided platform the formulas are to be corrected due to existence of indirect network externalities. The papers of Evans and Noel (2008)⁴³³ and Filistrucchi

432 Davies, P. and Garcés, E. (2010) Quantitative Techniques for Competition and Antitrust Analysis. Princeton U. Press

433 Evans D.S., Noel M.D. (2008). The analysis of mergers that involve multi-sided platform businesses. Journal of Competition Law and Economics, 4:3, 663-695

(2008)⁴³⁴ contribute to the issue. The authors deduce the following formulas for the case of two-sided non-transaction platforms. In this case it is reasonable to define two (related) markets, one in each side.

The papers differ in the assumptions about (i) the price changes, whether simultaneous price increases in both sides of the platform or not; (ii) the re-optimization of prices from feedback effects across platforms.

We take a simpler approach, in line with the basic Critical Loss exercise. We assume that each firm does not optimize the prices in the other side of the platform, as a response to the SSNIP in one side of the platform. In non-transaction markets, one should specify two markets. And the usual assumption on the hypothetical monopolist exercise is that firms and products outside the market does not react to the SSNIP. Interestingly even under the assumption of no price realignment within the platform from a SSNIP in one side of the platform, the indirect network effects play a very important role in the calculation of the Critical Loss. We indicate the possible bias arising from the violation of this assumption, following both authors.

In addition, we take the simple benchmark method for Critical Loss calculation. The CL is obtained by evaluating whether the SSNIP is profitable⁴³⁵. For a transaction market the critical loss expression would be the same as in the regular market, but using the total price increase SSNIP $(DP_A + DP_B)/(P_A + P_B) = X$ and total margin, a weighted average of the margins in each side.⁴³⁶

Here the cross network effects alter the CL formula significantly, so that the total price and total margins are relevant for calculating it. Using only the price and margin from the hypothetical platform on one side of the business could lead to a too narrow, or too large market, depending on the relative margins. Suppose we use side A price and margin only. The resulting critical loss will be lower than the actual critical loss if $M_A > M_B$.⁴³⁷ Using the high margin side information only to calculate the critical loss would lead to a too broad market, as the calculated critical loss is too small, leading to a higher likelihood of an unprofitable SSNIP. Symmetrically, using the low margin side information only to calculate the critical loss would lead to narrow relevant markets and an upward bias in the calculated market shares. If one of the prices are zero, the Critical loss formula would be based on a SSNIP for the non-zero price side, but include costs related to both sides.

In *non-transaction* markets, one relevant market should be specified, taking into account the network externalities. If we assume that elasticities are constant, a total price SSNIP of, say, 5% implies an equal 5% increase in each of the prices.

434 Filistrucchi, L. (2008). A SSNIP Test for Two-sided Markets: The Case of Media NET Institute*Working Paper #08-34

435 Algebraic details on the formulae are available upon request with the authors.

436 The same expression is obtained by Evans and Noel (2008), footnote 25.

437 Recall that we assume a symmetric SSNIP in both sides, so that total price increases by the SSNIP. We compare a mis-specified $CL_A^* = DP_A / (DP_A + (P_A - C_A))$ with the CL formula above.

$$CL_1 = \frac{X_1}{[X_1 + M_1]} - \frac{M_2 R_2 X_1 |\varepsilon_{12}|}{[X_1 + M_1] R_1}$$

where $M_i = (P_i - C_i)/P_i$; $R_i = P_i Q_i$ and $e_{AB} = (DQ_B/Q_B)/(DP_A/P_A)$ the cross price elasticity of demand across sides of the platform.⁴³⁸

The expression reflects the result in the cited papers that, if the cross network externality is positive (so that sides are complements, $e_{12} < 0$), the cross network effect reduces the Critical Loss. If the analyst does not consider the cross network effects the estimates Critical Loss will be too large and possibly the relevant market is defined as too narrow (a wrong CL analysis would find a price increase profitable, delimiting a market, while the correct CL would be smaller and the same price increase could become non profitable suggesting a broader marker).

While this case has not been explored in the papers cited, we can use the above expression to evaluate a side of the platform (A in our example) that charges a non-zero price, while the other side carries a zero price, i.e., $P_B = 0$.

$$CL_1 = \frac{\Delta P_1/P_1}{[\Delta P_1/P_1 + (P_1 - C_1)/P_1]} + \frac{C_2 Q_2 |\varepsilon_{12}|}{Q_1 [\Delta P_1/P_1 + (P_1 - C_1)/P_1] P_1}$$

The additional term is positive. The correct critical loss/ critical elasticity would be larger than the one calculated with a mis-specified demand model with no cross-network effects. The mis-specified model would delimit too wide markets. The zero price in side B and the cross effects generate a benefit for the losses generated by the price A increase, as the lower demand reduces the total losses.

On data requirements, cost and margin measures may be difficult to calculate as in many information based markets, where marginal costs are minimal and fixed costs significant. As an extreme case, Pike (2018)⁴³⁹ identifies situations where the firm profits (divided per quantity) from accounting information may be used.

Clearly the challenge to implement the above expressions is to calculate the price elasticities (as seen in Pike (2018)). A full-fledged demand system would be required, with additional cost information from all firms in the candidate market. In case of transaction markets with pass-through the 'standard' (for regular one sided markets) CLA is to be used where the quantities would be transactions and the price would be the sum of prices charged to the two sides of the platform. For transaction markets without pass-through the quantities would be transactions and the price for the demand estimation would be each side fees. In cases where transaction markets use two-part tariffs (a membership and a per unit fee) this would require additional care. If one of the sides is charged a zero price, demand estimation is relevant on the other side only. Note that as the number of transactions is the quantity variable, the fact that one price is zero does not alter the estimation significantly. For non-transaction matchmaking markets the

438 This expression is seen in Filistrucchi, 2008 see footnote 26) as a special case. Note that while the author claims it is also present in Evans and Noel, 2008 (see footnote 25), the latter paper expression (5) is actually different.

439 See footnote 4

challenge is to provide prices and quantities in comparable units. For non-transaction audience markets while two separate markets are estimated, demand analysis treat them as complementary products, so units of measurement and quantities must be compatible on each side. The business practice should be used. E.g., Argentesi and Filistrucchi (2007)⁴⁴⁰ use cover price per newspaper (abstracting from the fact that across the week the number of pages and prices vary) for the readership side and the number of advertising slots and the price per slot in Italy. Filistrucchi et al (2012a)⁴⁴¹ use advertising price per column millimetre and advertising area purchased for the Dutch market.

A common practice in delimiting markets is to use a residual demand approach for the hypothetical monopolist. If all the firms in the candidate market have a similar business model that allows comparability of prices and quantities this can be replicated. On the other hand, when the relevant market includes different business models (e.g. a platform that uses only membership fees in its transaction market, and other that use a per transaction fee) econometric exercises are not feasible.

Obtaining quantity and prices hinder a full-fledged demand estimation exercise. Filistrucchi (2018)⁴⁴² and Wismer and Rasek (2018)⁴⁴³ point to alternatives, such as customer surveys. For between platform diversion ratios, customer churning or natural experiments of supply interruption or entry effects could be used. Brekke (2018)⁴⁴⁴ provides an example from the Norwegian Competition Authority, in a newspaper merger. A survey was sent out to users of each side of the platforms (readers and advertisers) asking what would be the second option if their current newspaper was not available. This was used to calculate diversion ratios between firms, in the same side of the platform. The survey was carried out by phone (readers) or letter (businesses), given the relative number of each side. The author points out that the survey could have been used to infer about diversion ratios across platform sides.

Capturing cross-side deviations is more complex, argues Brekke (2018). Consumers might not be able to evaluate whether an increase in the volume of, say, advertising, would lead them to switch to another platform. While this could suggest that one of the cross-side effects is null, it may just reflect difficulties in recognizing this situation.

In all cases usual care on survey design is recommended to avoid steering respondents (framing bias), recollection bias and other. For example the questions should not create certain abstract situations so that members in each side of the platform would not be able to provide realistic answers.

Other market delineation tools used for markets with no cross-network effects may be used. Lianos and Genakos (2013)⁴⁴⁵ review the European experience and report the use

444 Brekke, K. (2018) Measuring market power in multi-sided markets. In OECD. In OECD, Rethinking Antitrust Tools for Multi-Sided Platforms. OECD.

445 Lianos, I. and Genakos, C. (2013). Econometric evidence in EU competition law: an empirical and theoretical analysis, in:

of price correlations, natural experiments and surveys in the first decade of the 2000 for general cases. In the case of multisided platforms, in addition to surveys, discussed above, natural experiments could provide interesting information for both demand elasticities and, more important, substitution patterns across products or competitors. A now classical example is the Ineos/Kerling case, cited by Lianos and Genakos, where plant accidents shut down production and forced substitution by consumers. Price correlations can be used, although there are known limitations such as the influence of cost and demand shocks unrelated to substitution patterns across products. The absence of prices in sides of the markets may restrict the analysis. In principle, if prices are available, for transaction markets total price correlation should be estimated, while for non-transaction markets price correlations for each market are required to inform about relevant market delineation.

2.2.2.2. Estimation of market shares, concentration and dominance

Once a market is delimited, in most jurisdictions a competition case would present the level of market power and the possible increase in market power from concentration indices. In the case of platforms the standard technique of measuring market shares and concentration for evaluating market power can be applied. In case of transaction markets, initial data for the analysis should be the value/ volume/ number of transactions; in the case of non-transaction markets the number of users at each side of the platform seems to be the most appropriate measure of the size of the market.

The Herfindahl-Hirschman index (HHI) is a commonly accepted measure of market concentration. It is calculated by squaring the market share of each firm competing in a market and then summing the resulting numbers. The indicator can range from close to zero to 10000. The higher the value of the indicator the more concentrated the market is. Markets are considered highly concentrated if HHI exceeds some threshold, which is, for example, HHI=2500 in Brazil and 2000 in Russia.

It is worth mentioning however that in two sided markets such concentration indices are less informative than in other markets. While there is a clear theoretical link between market power and concentration (HHI) in markets with homogeneous goods, such link is much weaker in markets of differentiated products. This gave rise to the Price Pressure Indices below and shifted the focus to diversion ratios between merging firms, without requiring competition authorities to explore in detail the pattern of substitution across non-merging firms in the relevant market.

Pike (2018)⁴⁴⁶ and Caffarra and Uwe-Kuhn (2018)⁴⁴⁷ point out that platforms usually bring sharp innovation to a type of good consumed. This creates a challenge to compare its product with other products. A new business model is often what the firms brings to the market. Products are often extremely differentiated across platforms, so the difficulties

Handbook on European Competition Law, chapter 1, pages 1-137 Edward Elgar Publishing.

446 See footnote 4

447 Caffarra, C.; Kuhn, K-U. (2018). The competition analysis of vertical restraints in multi-sided markets. In OECD, Rethinking Antitrust Tools for Multi-Sided Platforms. OECD.

in delimiting markets in differentiated goods is amplified in a two-sided market setting. This leads many authors to the conclusion that little emphasis should be placed on market power presumptions from concentration. Some even come to the suggestion that competition authorities should skip the market definition exercise. Yet in many jurisdictions the market definition is required to measure dominance (market shares in Brazil, e.g.) or to base fines in abuse of dominance cases (Russia, e.g.).

Two sided markets pose additional challenges: cross-network externalities imply that market power in one side would reinforce market power in the other side (when looking at two interrelated markets), even if the level of concentration is low on the other side; network externalities in each side (with single-homing) may generate tipping point/winner takes all situations that create significant entry barriers to other consumers, even if the market is not near monopoly on that side; single-homing or multi-homing can influence the competitive assessment and the extent it exists should be evaluated (Wismer and Rasek, 2018⁴⁴⁸).

Last but not least, as mentioned in the previous section, even a monopoly position of an MSP on a market should not be associated with its market power keeping in mind the dynamic nature of competition. Innovations and development of new products are the result of competition on the merits. Improved products and services in competitive markets displace outdated ones. This dynamic competition cannot be measured by concentration indexes. Actually, no tools have been developed to assess dynamic effects in a multi-sided markets setting.

2.2.2.3. Modified GUPPI to unilateral effects assessment

The Upward Pricing Pressure (UPP) concept was proposed by Farrell and Shapiro in 2010⁴⁴⁹. The idea can be traced back to Salop and O'Brien (2001)⁴⁵⁰. UPP is the difference between two pricing incentives of a merger: an upward pressure on prices due to the loss of competition and downward pressure on prices due to merger-related rise in production efficiency (marginal cost decrease). The formula is given by:

$$UPP_1 = (P_2 - C_2)D_{12} - E_1C_1$$

where 1, 2 are differentiated products supplied by corresponding merging companies; D_{12} is the diversion ratio from product 1 to product 2, P_2 is the price of product 2, C_1 and C_2 are the marginal costs of product 1 and 2, respectively, and E_1 is a measure of possible merger-related cost decrease in producing product 1; UPP_1 is the upward pricing pressure for the price of product 1. As long as $UPP_1 \geq 0$ the merging firms will have incentives to increase the price of product 1.

Alternatively, the Gross Upward Pricing Pressure Index (GUPPI) proposed by Salop and

448 See footnote 7

449 See footnote 19

450 Salop, S; O'Brien, D (2000) Competitive Effects of Partial Ownership: Financial Interest and Corporate Control, 67 ANTI-TRUST LJ. 559 69

Moresi in 2009⁴⁵¹ does not grant an efficiency credit and present the information as a percentage price increase for firm 1:

$$GUPPI_1 = \frac{P_2 - C_2}{P_2} D_{12} \frac{P_2}{P_1}$$

In fact, the formula takes into consideration the upward pressure on prices only with no efficiency allowance. The GUPPI will always be positive if the merging parties' products are substitutes. Practical use as a tool for merger screening, requires some threshold level to be specified by competition authority as suggested by the authors. Farrell and Shapiro suggest up to 5%, as these are likely efficiencies in many mergers.

Affeldt et al. (2013)⁴⁵² extend UPP and GUPPI for the case of merging *non-transaction platforms*. Price changes in multi-sided markets involve both direct demand effects across firms, as in one-sided markets, and also network externalities effects across sides. While the analysis can become complicated easily, as the formulae must account for two firms (1 and 2) and two sides (A and B). We take the authors' example of a newspaper as a platform. The merger affects both the advertising (A) market and the readership (R) market. The demand function for each side and each firm depend on all prices. For example $Q_1^A = D(P_1^A, P_2^A, P_1^R, P_2^R)$. If positive cross side effects are present, the effect of P_2^R on Q_1^A is positive, as firms are substitutes and platform sides are complements.

The authors show that in case of merger between newspaper 1 and newspaper 2, the UPP condition for newspaper 1 in the readership market is given by:

$$UPP_1^R = (P_2^R - C_2^R)D_{12}^{RR} - E_1^R C_1^R + (P_2^A - C_2^A)D_{12}^{RA} - E_1^A C_1^A D_{11}^{RA}$$

The first two terms are the standard UPP measure for one-sided markets as seen above. The additional two terms are generated because of the cross-network effect. measures the increase in sales in firm 2 advertising business from a price increase in firm 1 increase in readership (newspaper cover) price. This is likely to be positive in the case of newspapers, but generally can take any sign depending on the nature of the network externality. The last term is of particular interest: it measures the efficiency gains in the other side of the platform, multiplied by the volume sales relative change, induced by and an increase in newspaper cover price. This term is likely to be negative in this example: a price increase in newspaper cover price reduces readership making it less attractive to advertisers. The total effect of the cost savings in the advertising side may be to increase readership prices.

GUPPI measures, which ignore efficiency gains, for two-sided markets can be written:

$$GUPPI_1^R = M_2^R D_{12}^{RR} \frac{P_2^R}{P_1^R} + M_2^A D_{12}^{RA} \frac{P_2^A}{P_1^R}$$

Where M_2^R and M_2^A are the profit margins (in percentage) of newspaper 2 in the mar-

451 See footnote 20

452 Affeldt P., Filistrucchi L., Klein T.J. (2013). Upward pricing pressure in two-sided markets. The Economic Journal, 123(572), 505-523

kets R and A respectively. Interestingly, if the readership side has below cost pricing the GUPPI/UPP formulas will suggest a possibly negative price change after the merger, as reducing the readership reduces losses across platforms. This of course would be compensated from the cross-platform margin.

For *transaction platforms* it is not difficult to provide a UPP like formula, with no allowance for efficiencies

$$UPP_1^R(T) = [(P_2^R - C_2^R) + (P_2^A - C_2^A)] D_{12}^{RR}$$

Where $D_{12}^{RR} = (\partial D_2^R / \partial P_1^R) / (\partial D_1^R / \partial P_1^R)$. Recall that the demand function is $D_i^A(P_i^A, P_j^A) D_i^R(P_i^R, P_j^R)$. As in the usual UPP formula, the margin on the other firm and the diversion ratio across firms are central. In a transaction market the relevant margin is the total margin, or the price in one side of the platform minus the adjusted, 'opportunity cost' in the words of Rochet and Tirole (2006)⁴⁵³ $C_2^R - (P_2^A - C_2^A)$. The diversion ratio refers to diversion across firms, comparable to the simple one sided UPP. Compared to the non-transaction market formulae above, there is no cross-side diversion ratio as in this model transactions require one-to-one in each side.

2.2.2.4. Tests for exclusionary abuses in MSP

A number of tests aimed to sort out pro-competitive from anti-competitive exclusionary conduct of a dominant company have been proposed by scholars for traditional (one-side) markets (OECD, 2005)⁴⁵⁴. These include:

- a) *the profit sacrifice test (the "but for" test)* which states that conduct should be considered unlawful when it involves a profit sacrifice that would be irrational if the conduct did not have a tendency to eliminate or reduce competition.
- b) *the no economic sense test (the NES test)* which states that a conduct should be unlawful if it would make no economic sense without a tendency to eliminate or lessen competition.
- c) *the equally efficient firm test* which states that conduct should be unlawful if it would be likely to exclude a rival that is at least as efficient as the dominant firm is.

The above tests are used but subject to criticism for non-two sided markets. Test a), the profit sacrifice "but for" test, is criticised in several ways. First, short run profit sacrifice does not always follow exclusionary conduct, thus the test is under-inclusive. Second, profit sacrifice may follow a conduct that formally restricts competition while increasing social/consumer welfare. So, the test may be over-inclusive as well.

In contrast to the "but for" test the b) NES test prohibits the conduct that eliminates competition and provides an economic benefit to the defendant only because of a competition restriction effect, regardless of whether the conduct is costless. Thus the test avoids the criticisms directed at the profit sacrifice test related to ambiguous relation-

453 See footnote 21

454 OECD (2005). Competition on merit. OECD Roundtables. <http://www.oecd.org/competition/abuse/35911017.pdf>

ship between exclusionary conduct and economic results of a company. At the same time the test is still weak in terms of balancing of positive and negative welfare effects of a conduct.

For the case of test c), the problem of efficiency measurement and comparison when products are differentiated and business strategies of companies differ is well known, irrespective of the 'sidedness' of the market. The criticism of the test is related also to the fact that logically the exclusion of less effective competitors should not be considered harmful for competition. However in many cases a dominant company is more efficient than its smaller competitors and new entrants need time to reach the level of efficiency comparable to the one of existing firms. Results of the test would not treat their exclusion from the market illegal despite their potential ability to compete and improve social welfare.

The above tests implicitly use the pricing results of firms with market power. We should expect firms with market power to price above marginal cost, following the Lerner Index. The same approaches could in principle be applied to MSP, taking the mentioned weaknesses into consideration. However multi-sidedness adds restrictions on the applicability of the tests because of network effects and interrelation of markets. All types of price-cost tests are problematic when applied to MSP because pricing rules with market power can generate below cost pricing in one side of the market, with no exclusionary intent. Platforms may price one side of the market with a price above the opportunity cost of servicing this market, that includes not only the actual direct cost of the service but the loss in profits from a higher price in the other side of the platform, given cross-network effects. The Lerner index as usually measured can possibly overestimate and underestimate the degree of market power. In general, if positive cross-side platform effects are present, the Lerner index can be negative if using information from one side of the market only.

Put in another way, the two sided nature of these markets, with their cross-price elasticities require sharp changes in the tools for the analysis of exclusionary practices (as well as excessive pricing), compared to regular analysis. According Rochet and Tirole (2006)⁴⁵⁵, in transaction platform cases the price level (the sum of prices in both sides) is the competitive measure that reflects market power, not the price in each side. The relative prices are used to balance the market, in the sense of attracting consumers, in proportions to their relative elasticities to maximize the number of transactions. Fletcher (2007)⁴⁵⁶ thus does argue that the Areeda/Turner guidance that below marginal cost price in a single side of the market does not inform of predatory pricing. One should consider the sum of prices and the joint marginal cost to evaluate whether negative margins are present.

455 See footnote 21

456 Fletcher, A. (2007). Predatory pricing in two-sided markets: A brief comment. *Competition Policy International*, 3(1), 221-224

For non-transaction two sided markets, Behringer and Filistrucci (2015)⁴⁵⁷ come to a parallel conclusion. Given the cross network externalities and the different, possibly unrelated prices, below marginal cost pricing is a natural outcome of the internalization of cross-network externalities even for a monopoly. The monopoly case is interesting because when there is a single seller, predation does not make sense. The costs in each side and the prices on each side have to be taken into account when evaluating below marginal pricing. In non-transaction markets there is the complication that units of measurement may differ across sides and that pricing is often not related to volume (subscription fees not pay per view pricing in media streaming or cable TV).

An extra uncertainty appears in case of MSP due to the network effect when the number of users becomes an important determinant of the platform efficiency (whatever it is measured). Keeping in mind that a rival should be of the same size, it is unlikely that an equally efficient rival would be found in the market. In the absence of equally efficient competitor the own company's prices and costs are sometimes used and thus the test becomes similar to the "but for" one. On the other hand, by ignoring the effect of the size a competition agency may overlook that in many cases a dominant company is more efficient than its smaller competitors and new entrants need time to reach the level of efficiency comparable to the one of existing firms. The test conclusion would be not to treat their exclusion from the market illegal despite the entrants' potential ability to compete and improve social welfare as in the standard one sided case.

In both transaction and non-transaction markets, the differences in prices from costs can be rationalized from the business model of the platform. These business models should recognize the strong cross-side effects of platforms. At the same time, they bring solutions to of possible informational asymmetries problems in that market. These solutions often provide the central attractiveness of the platform model. For example, in the case of online taxi applications, such as Uber, the reputation system for both drivers and riders, and the third party (the platform) price setting rules, generate great value to all sides. These are market making businesses that create value and efficiency.

2.2.2.5. Tests for efficiency effects

Where cross-platform network effects are strong, mergers of multi-sided platforms might generate efficiencies if they combine separate user bases and increase interoperability. Chandra and Collard-Wexler (2009)⁴⁵⁸ argue that a merged platform might better internalize cross-platform externalities and thus set lower prices to both sides of the market, attracting new users and expanding the market. Andreu and Padilla (2018)⁴⁵⁹ reason that new technology developments resulting from a platform merger may increase consum-

er surplus even while the prices increase, due to creation of a higher quality product. Estimation of efficiency effects might be demanded in investigations of alleged violations of competition law as well. When a conduct is not illegal per se some welfare balancing might be applied to test if the negative effects of the conduct on consumer welfare are outweighed by pro-competitive welfare effects (increase in the company's efficiency, new technology development etc.). The criticism of the approach is related to the technical difficulties of identification, estimation and comparison of the effects. The *Disproportionality test*⁴⁶⁰ states that conduct is anticompetitive when it results in harm to competition that is "disproportionate" to consumer benefits and to the economic benefits to the defendant. This approach remains open the questions about how big the "disproportion" should be and what to do in case they cannot be compared (and even measured, i.e. in case of product quality improvement). The *Elhauge efficiency test*⁴⁶¹ is an attempt to omit the problem of balancing the effects. When exclusionary effect and increase in the defendant's dominance are observed the test asks whether a dominant position is being enhanced or maintained because the defendant is improving its own efficiency (lawful), or because the defendant is impairing the rival's efficiency (unlawful). In practice, however it is very unlikely that an unambiguous cause-and-effect relationship can be identified. This leaves a lot of space for appeals and increases costs of litigation. In the case of MSP it becomes even more difficult as efficiencies generated on different sides of the market should be taken into consideration.

Last, the use of simulation tools to assess the likely efficiencies of a merger for users on each side of the platform requires agencies to estimate cross-platform effects. Surveys or demand estimations can be used to generate these estimates in the way described for market delineation, as mentioned above. In some circumstances tools that do not require estimation of the cross-platform effects – such as event studies – might also be applied.

2.2.3. Conclusion

The growing importance of multisided platforms (MSP) as a leading business model in the digital economy urges competition authorities to update and adapt their tools to evaluate possible anticompetitive effects in both mergers and abuse of dominance cases. The goal of this paper was to present analytical tools to manage competition policy analysis in MSP highlighting the required changes from the usual one sided markets frameworks and tools.

MSPs organize interactions between users so to internalize cross-side network externalities. The actual interaction form and the pricing strategy of the MSP influence the analysis. Learning about the business model of the platform (or platforms), a taxonomy of MSPs from the interaction of and the pricing to the sides of the platform becomes an important starting point. Recognizing whether the MSP under scrutiny is a transaction

460 <https://www.justice.gov/atr/competition-and-monopoly-single-firm-conduct-under-section-2-sherman-act-chapter-3>

461 (OECD, 2005) – see footnote 47

or non-transaction platform steers the decision as to whether considering one relevant market or two relevant markets, respectively. Supply side characteristics of MSP are relevant as well, with the presence of economies of scale and learning by doing, and innovation intensive business models.

The cross-side network effects are central when evaluating substitution patterns and price effect for each platforms and, more important, cross-side effects. These effects influence market definition under the HM test and SSNIP tests. For example, if cross side effects are positive, a price increase on one side that is profitable under a one-side analysis might become non-profitable, as the decrease in sales on side A of the platform reduces sales on side B, typical of cross-side effects, that feedback and reduce sales further on side A. Not taking into account the cross-platform effects would lead to too narrow markets.

Supply side characteristics of MSP, shared with other digital businesses are relevant for understanding platform competitive leverages. These platforms often experience scale and learning economies. This interacts with the innovation based competition dimensions and large startup or fixed costs.

After delimiting markets, concentration measures may not be informative of the market power of the platform. First, platforms are often innovation-based, disrupting businesses and market shares may change rapidly as in any dynamic competition market. Second, MSP are differentiated products, where markups are weakly associated with concentration measures. Third, pricing formulas in transaction or non-transaction platforms show that standard Lerner indices are invalid when calculated using costs (or prices) from one side of the platform. Lerner indices for MSP must incorporate the cross-side effects and the balancing need of the platform to increase demand on one side with higher demand on the other side.

Inferences on anticompetitive price effects from mergers can be obtained expanding price pressure indices for two sided platforms. The GUPPI/UPP like formulae highlight that usual one-sided mergers formulas omit the cross-side effects. These cross-side effects amplify the price pressure increase, say, on price of side A of the merged platform 1, as an increase in demand on side A of merged platform 2, would boost sales in side B of platform 2. This second effect reinforces the incentives to increase prices in side A of platform 1. Only if the cross side effects are not present using the standard formula would not underestimate the effects.

As in any other market, exclusionary practices can be observed in MSP. The nature of MSP requires four changes in the usual investigative tools and effects analysis. First, Price-cost comparisons in MSP are not recommended, as optimal pricing formulas, with no exclusionary or abusive intent generate below cost pricing. The requirement that variable costs from both sides to be taken into account generate additional difficulties as (i) these costs may be hard to measure; (ii) many digital markets operate basically with zero marginal costs and accounting attempts to allocate the fixed costs across platform sides may create statistics that have not been relevant for decision making. Second,

the network effects and issues of single- and multi-homing, generate ‘tipping’ points in the demand for a platform. This can both consolidate exclusionary practices, and make them more effective. Third, platforms often create markets, solving information problems in markets. This institutional role of the platform can generate efficiencies (creating a market) that are very hard to quantify and balance with respect to competition across platforms or a benchmark without the platform. Fourth, learning-by-doing technologies generate dynamic competition exclusionary opportunities, as younger firms have cost disadvantages that may not disappear over time or predatory pricing practices recoup period have lower costs. These business dimensions become central in the analysis of exclusionary practices.

Last but not least, competition policy analysis of MSP should recognize the dynamic nature of competition in such businesses. MSP are often innovations that create monopolization, while at the same time such dominance can be quickly erased by new platforms and business models. While new ways of doing business induce new analytical tools, such innovation markets are not unknown to competition authorities. A look at the less used tools in the known toolbox would help meet the challenge of competition policy analysis of MSP.

Chapter 3: The Private governance of Digital Value Chains

Ioannis Lianos & Klaas Hendrik Eller

3.1. Introduction

While the later chapters of this Report will explore regulatory pathways vis-à-vis digital platforms and ecosystems, this chapter will explain how platforms and ecosystems are animated based on a private governance regime that combines legal, social and technological layers of governance. It will detail to what extent the design of such private governance infrastructure impacts upon the value generation and distribution for the respective platform. It uses a literature review of contributions from economics, economic sociology, and contract governance fused with the 'global value chain' analytical framework to establish a typology of private governance of digital platforms. This typology is tested and explained against the background of an empirical study of the private governance of major digital platforms and ecosystems (cf. Annex).

3.2. A 'Natural order' rhetoric to the private governance of platforms and ecosystems?

Discussions over the private governance of digital platforms and of their ecosystems are merely driven by what we can name the 'natural order' rhetoric, which takes the private governance of the platform, or its ecosystem, as a given, as a natural outgrowth of the business plan adopted by the digital platform, an open or a closed/'walled garden' or something hybrid, which benefits from some type of immunity ('forbearance regime'⁴⁶²) from public intervention, in the form of antitrust or regulation, on the belief that this would jeopardize the innovation and growth generating potential of the digital entrepreneurship, in accordance with the Schumpeterian vision of the role of the State. It is quite ironic that such a 'natural order' vision, which has been previously used to justify the expansion of the market form of organization as the best mechanism to reward productivity and ensure allocative efficiency⁴⁶³, has been used again, here with the different purpose of justifying the superior efficiency (dynamic, productive and allocative) of the private orders established by the digital platforms and emerging out of a Schumpeterian process of creative destruction. According to this view, to the extent that some degree of horizontal competition exists

462 If we follow the terminology used by O. Williamson, *The Mechanisms of Governance* (OUP, 1996), 100.

463 For a poignant critique, see BE Harcourt, *The Illusion of Free Markets – Punishment and the need of Natural Order* (Harvard University press, 2012) criticizing 'the 'illusion' of 'free markets' perceived as a natural order that pre-exists regulation'.

between platforms or different ecosystems, there should be no state intervention, in particular if this will aim to regulate the capture of value by the digital platforms within their ecosystems. Hence, the law stays agnostic as to the allocation of value between the members of the ecosystem, and accepts as justified by superior economic efficiency the existing allocation of risks and rewards between the members of the digital ecosystems or between the various components of digital platforms.

These various ‘natural order’ inspired justifications of regulatory immunity result from an economic conception of the firm, as the most efficient form of organization in the presence of transaction costs and thus costs in using the market (decentralized) system, or of similar approaches explaining the benefits of vertical integration and, more generally, viewing positively the expansion of the boundaries of the firm (centralized form of governance) vis-à-vis those of the market (decentralized form of governance), if these two are conceived as the two main poles of organization (3.2.1.). However, such ‘natural order’ rhetoric may be challenged by the emphasis put, by some business studies literature, on the role of agency and in particular business strategy in explaining the way firms and ecosystems are internally organized. This literature does not share the ‘natural order’ perspective and does not assume the superior efficiency of the internal organization of these private systems of governance (platforms and/or ecosystems). By putting emphasis on the strategic component, this literature opens the black box of the private governance of these platforms/ ecosystems and the way this may be influenced by strategies of value capture. Hence, it puts emphasis not only on value generation but also value capture as important explanatory factors in understanding how these private governance regimes came to exist (3.2.2.).

3.2.1. Transaction cost economics and private governance

As it is well known in Transaction Costs Economics (TCE) literature, Markets and Hierarchies are not distinct concepts but different poles of a *continuum*. Oliver Williamson also introduced a third concept in this taxonomy of organizational forms by suggesting the concept of ‘hybrids’ for forms of organization that do not correspond to the characteristics of the previous two forms⁴⁶⁴. This term, still highly imprecise, covers a variety of organizational forms, such as alliances, collective trademarks, networks, partnerships and relational contracts⁴⁶⁵ which do not institute hierarchies, as each of the participants retains its autonomy, and do not institute markets, as there are formal or informal mechanisms that are set in order to facilitate a long-term coordination and cooperation between the different entities forming the hybrid⁴⁶⁶.

464 O Williamson, ‘Comparative Economic Organization: The Analysis of Discrete Structural Alternatives’ (1991) 36 Administrative Science Quarterly 269.

465 S Deakin et al., ‘“Trust” or Law? Towards an Integrated Theory of Contractual Relations Between Firms’ (1994) 21 Journal of Law and Society 329, 334–35; I R MacNeil, ‘Contracts: Adjustment of Long-Term Economic Relations Under Classical, Neoclassical, and Relational Contract Law’ (1978) 72 NW. U. L. REV. 854, 857.

466 C Ménard, ‘The Economics of Hybrid Organizations’ (2004) 160 Journal of Institutional and Theoretical Economics 345,

These different forms of organization give rise to different types of contractual arrangements in this context. Because of the difficulty of considering *ex ante* all the possible ‘consequential disturbances’ that may happen in the future in the context of these complex economic relations, involving significant investments that are specific to the relation (‘asset specificity’), contracts will inevitably be incomplete⁴⁶⁷.

‘Long term incomplete contracts require special adaptive mechanisms to effect realignment and restore efficiency when beset by unanticipated disturbances’⁴⁶⁸.

Although these adaptive mechanisms perfect the contract between the parties, at the same time, they impose important restrictions on the autonomy of the parties in the market. If the specific investments are important and there is an important risk of opportunism, the transaction costs will be important and a hierarchy may emerge, thus justifying the expansion of control by the management of the firm.

For the proponents of TCE, the legal regime should take account of the specificities of each of these forms of organization and the existence of transaction costs that would justify, from an economic efficiency perspective, a more integrated form of control and coordination between the parties to the transaction. Accordingly, the law applicable to the internal organization of the firm or hierarchy should be forbearance. Williamson explains

‘whereas courts routinely grant standing to contracts between firms should there be disputes over prices, the damages to be ascribed to delays, failures of quality, and the like, the courts have the good sense to refuse to hear disputes between one internal division and another over identical technical issues. Access to the courts being denied, the parties must resolve their differences internally, which is to say that the firm becomes its own court of ultimate appeal’⁴⁶⁹.

There are two reasons that mainly justify the law of forbearance:

‘(1) parties to an internal dispute have deep knowledge – both about the circumstances surrounding a dispute as well as the efficiency properties of alternative solutions – that can be communicated to the court at great cost, and (2) permitting the internal disputes to be appealed to the court would undermine the efficacy and integrity of hierarchy’⁴⁷⁰.

The identification of these different forms of organization and of their corresponding regimes of contract law has important implications for competition law analysis if one is to adopt this ‘natural order’ rhetoric. Hence, the restriction of the autonomy of some of the members of these hierarchies or network forms of organization are simply viewed

347–350.

467 O Williamson, ‘Comparative Economic Organization: The Analysis of Discrete Structural Alternatives’ (1991) 36 *Administrative Science Quarterly* 269, 271.

468 O Williamson, *The Mechanisms of Governance* (OUP, 1996) 96.

469 O Williamson, ‘The Economics of Governance’ (2005) 95 *American Economic Review* 1, 10.

470 O Williamson, *The Mechanisms of Governance* 100.

as governance tools that aim to avoid organizational failures. Thus, according to this view, they bring transactional efficiencies. Consequently, in the absence of significant horizontal market power, competition law (or economic regulation) should stay away from intervening, as this may compromise the internal organization of this form of governance and the transactional efficiencies this may bring and the entrepreneurial innovation brought by the digital platform. The scope of competition law intervention may be slightly more important in the situation of a network than in that of hierarchies, but for both the 'natural order' rhetoric does not justify the intervention of the State.

The distinction between network and hierarchies should not, however, be overstated. Networks may evolve towards a loose form of hierarchy as they are subject to cyclical developments following which the most powerful participants may bring the network itself under control and create a situation of hierarchy⁴⁷¹.

Property rights theories of the firm also adopt this 'natural order' perspective, viewing the various contractual restraints as control mechanisms for complementary assets⁴⁷², even in situations where there is no asset specificity. As Hart pointed out,

'in a world of transaction costs and incomplete contracts, ex post residual rights of control will be important because through their influence in asset usage, they will affect ex post bargaining power and the division of ex post surplus in a relationship', division which will, in turn, 'affect the incentives of actors to invest in that relationship'⁴⁷³.

By emphasizing the incentives to innovate of the various parties, in particular the digital platforms or ecosystem orchestrators, property rights approaches of the firm may reinforce and expand the call for forbearance and thus expand the scope of immunity from competition law and regulation.

3.2.2. Resource based theory of the firm and GVC approaches

The 'natural order' approaches envisioned above give little emphasis on the strategic element explaining the emergence and expansion of private governance regimes in the digital economy. Under certain circumstances, contractual or other internal governance instruments developed by the platforms and ecosystems orchestrators to govern and manage their organizations may form part of a strategic effort to limit competition by raising barriers and marginalising competing platforms and ecosystems through strategic foreclosure, thus limiting horizontal competition and leading to an exercise of market power, affecting the generation of value. These approaches ignore the impact of these strategies on vertical competition, which relates more to distributional effects (relating to the allocation of the surplus value) or 'pecuniary externalities' that, accord

471 HB Thorelli, 'Networks: Between Markets and Hierarchies' [1986] 7 Strategic Management Journal 37.

472 O Hart and J Moore, 'Property Rights and the Nature of the Firm' (1990) 98 Journal of Political Economy 1119.

473 O Hart, 'An Economist's Perspective on the Theory of the Firm' (1989) 89 Colum. L. Rev. 1757, 1766.

ing to neoclassical price theory (NPT), should be ignored if one focuses on economic efficiency⁴⁷⁴.

However, one needs to also integrate the impact that such contractual or governance tools may have on the capture of value by the different members and components of these private governance systems, if it is important to understand the full social costs of such systems. Furthermore, one may take a non- economic efficiency- based perspective for competition law, promoting other values such as fairness, in which case the distribution of the total surplus value between the different segments of the value chain may become an important concern for competition law, either because of considerations relating to equality of opportunity concerns, or because substantial restrictions to vertical competition may impact on productivity, as an overwhelming percentage of the total surplus value is captured by 'superstar' large firms that enjoy tremendous levels of profitability, without however these accumulated profits being used for productive investments, that could ultimately generate value for consumers and the public at large. In addition, empirical evidence for each of these 'natural order' theories explored in 3.2.1. is relatively ambiguous and quantifying the welfare effects of such private governance regimes remains challenging.

Resource-based approaches of the firm focus more on the strategic element by attempting to explain firm's expansion⁴⁷⁵. The theory perceives firms as having idiosyncratic, meaning not identical, strategic resources. These resources are not perfectly mobile. The primary objective of business-level strategies developed at the firm-level is to create sources of sustainable competitive advantage. Strategies build on the resources, assets and capabilities of firms. Assets can be physical (e.g. plant equipment, location, access to raw materials), human (e.g. training, experience, judgment, decision-making skills, intelligence, relationships, knowledge), and organizational (e.g. culture, formal reporting structures, control systems, coordinating systems, informal relationships). Firm's capabilities are usually considered as a 'bundle' of assets or resources to perform a business process (each of them composed of discrete individual activities). For instance, the product development process involves discrete modules of activity, such as conceptualization, product design, pilot testing, new product launch in production, etc. The firm's most important capabilities are called competences. The firms adopt strategies in order to gain a sustainable competitive advantage. Thus may be understood as a process of developing distinctive competences, competitively valuable capabilities that make a company perform better than its rivals in the industry, thus ensuring its ability to gain abnormal profits for a significant period of time.

This focus on strategy and the conceptualization of the firm's organization as related to the implementation of modular tasks by the resource-based theory of the firm have

474 This is the main lesson of the so- called Coase theorem, which assumes a world of zero transaction costs and individuals that are able to bargain and internalize technological externalities, leaving aside pecuniary externalities: RG Holcombe and RS Sobel, 'Public Policy Toward Pecuniary Externalities' (2001) 29(4) Public Finance Rev 304.

475 B Wernerfelt, 'A Resource- based View of the Firm' (1984) 5(2) Strategic Management J 171; KC Prahalad and G Hamel, 'The Core Competence of the Corporation' (May- June 1990) Harvard Business Rev 79.

profoundly inspired the Global Value Chain (GVC) literature that has emerged out of the study of global supply chains, first in commodities and then in more composite products, taking a political economy perspective. However, the added value of the GVC theory, which breaks with the ‘natural order’ rhetoric of the TCE and property rights’ approach and their belief that private governance systems are developed organically in view of the specific characteristics of transactions and for this purpose are assumed economically efficient is the emphasis put on value capture and more generally the distribution of value that may be an important explanatory factor for the emergence of a specific organization structure.

There are differences however between the resource-based view of the firm and GVC. While the resource-based view of the firm focusses on specific (technological, economic, strategic...) resources, the GVC approach describes an organizational reality, namely the fragmentation of a single economic entity into multiple tiers of suppliers operating in various jurisdictions⁴⁷⁶. Economic trends of outsourcing, offshoring and vertically integrated trade are reflected in an organizational form which – unlike previous cases of an “international division of labour”⁴⁷⁷ becomes institutionalized to a high degree and actually forms the “central nervous system”⁴⁷⁸ of the World Economy. Across industries of production and services as diverse as textile, clothing, retail, footwear, automotive, food and agriculture, seafood, fisheries, electronics, construction, tourism, horticulture or transport, global value chains form the organizational backbone.

Today, “global value chain” refers to both an economic paradigm and a conceptual framework that brings together insights from a broad range of disciplinary fields beyond management, including *inter alia* organizational and economic sociology, political economy, geography, anthropology and development studies. This framework has, however, gained high practical importance by providing the conceptual underpinning of numerous policies and strategic analyses at a national and international level. Individual countries rely on the GVC framework to explore chances of “upgrading”, ie of capturing a more significant share of a given value chain by providing those services that add a relatively larger part of value. Hence, GVCs can ideally serve as an engine of development and technology transfer, thereby offering an opportunity for poverty reduction and job creation by transforming informal to formal economies. In addition, international organizations draw on the GVC framework⁴⁷⁹

to assess cross-cutting issues of economic development, trade and investment policies, sustainability, workers' rights, waste and resource circulation as well as gender equality and inclusion. Besides and more generally speaking, GVC analysis has become a heuristic to understand the interconnectedness of global economic activity across time and space and enables to point out dynamics between seemingly unrelated norms, actors and processes. Through this, GVC analysis calls to reformulate policy tools as well as legal concepts to adjust them to the networked-type of the World Economy. This concerns concepts classically referring to isolated and distinguishable markets (such as "abuse of dominance") as well as legal concepts that assume bilateral relations isolated from a transactional context (such as most contemporary theories of contract and also theories of the firm).

While GVC analysis provides many inspirations for theories of the firm, it does not itself claim to fall into this category. Much of its theoretical ambition is devoted to illustrating a dissolution of boundaries of firms based on strategic alliances that combine inter- and intra-firm relations and let relations with key-turn suppliers become so institutionalized that they appear rather as an entity than as individual agents. GVCs invite fundamental questions of agency: Lead firms use various tools, both formal and informal, legal and para-legal, to "govern" their supply chain, yet at the same time, GVCs can easily reach degrees of complexity that are (sometimes deliberately) beyond the control of a single actor. For instance, chip manufacturer *Intel* uses more than 19,000 suppliers in over 100 countries to provide direct material but also tools, machines, logistics and packaging.⁴⁸⁰

Likewise, *Philipps* uses tens of thousands of suppliers many of which operate as heads of "supply chains within supply chains". This ultimately challenges a linear trajectory of a chain as suggested by management studies (which are concerned with the tracing of physical sub-parts and commodities, not social processes and externalities of production).

3.2.2.1. Emergence of the GVC framework

The intellectual origins of the GVC framework and its predecessors stem from World Systems Theory, a historical theory of capitalist development that strongly draws on a spatial distinction between core and periphery to explain hierarchies and power differentials in world trade. The first related concept, "global commodity chain", was developed by Terence Hopkins and Immanuel Wallerstein in the late 1970ies to challenge methodological nationalist understandings of capitalism which focusses on the sequential stages that bridge national markets and global trade.⁴⁸¹

Against this dominant view, they suggested "a radically different presumption", namely to take as starting point a "linked set of processes ... (called) a commodity chain" that includes, eg in the case of clothing, "the manufacture of the cloth, the yarn, etc., the cultivation of the cotton, as well as the reproduction of the labor forces involved in these productive activities". The ground-breaking novelty of this was to oppose the stat-

⁴⁸⁰ Cf K. Crawford/V. Joler, *Anatomy of an AI System* (2018), available at anatomyof.ai/img/ai-anatomy-map.pdf.

⁴⁸¹ T. Hopkins/I. Wallerstein, *Patterns of development of the modern world-system*, Review 1 (1977), 111-145 (128).

ist paradigm of social sciences with its stable units of analysis by taking as starting point a construct that locates and moves between and across such levels of analysis. A particular ambition was to apprehend global-local dynamics.

A subsequent iteration of the concept was coined by Gary Gereffi as “global commodity chains” (GCC), shifting focus from a macrohistorical perspective to industry- and firm-centered analysis of economic organization. With this new framework, Gereffi introduced a distinction between so-called *producer-driven* and *buyer-driven chains* which for long represented the dominant typology. Based on the relative importance of a supplier within a chain, ie the (in)dispensability of the resources a supplier provides, this typology sought to express where power is located within a chain.⁴⁸² Classical examples for buyer-driven chains are textiles and agri-food⁴⁸³ where transaction-specific knowledge is low while producer-driven chains can be found in more technology-intensive industries such as automotive, computers or entertainment technology.⁴⁸⁴

This implied two significant reorientations of the framework: Firstly, GCCs were understood as a form of economic organizing closely linked to technological advances and trade liberalization in the second half of the 20th century, and not similarly as an evolutionary stage in the development of capitalism as pointed out by World Systems Theory with reference to the “long 16th century”. Secondly, the objective of commodity chain research has moved towards an understanding of the organization of global industries, its relevant actors and mechanisms of value capture and distribution. GCC analysis posits that linking up with lead firms in the industry is the most promising path towards development. This has spurred numerous case-studies on national development prospects essentially in Asia, Africa and Latin America and generally created a consistent and policy-oriented body of scholarship under GCC and even more so under the latest refinement of the framework as “global value chains” (GVCs).⁴⁸⁵ Its central addition is the concept of “value-added”: Under ever more competitive global market conditions, it is not the quest for cost reduction per se, but product differentiation and the strategic localization and capture of value-adding segments of the production process that guides market behaviour.⁴⁸⁶ Closely linked to mapping of value-added is the concept of “upgrading”, namely the aspiration of chain actors and national economies to move towards high value-adding segments of a chain (“economic upgrading”) and improve the social quality of employment (wages, workplace safety, inclusion, “social upgrading”) so that they do not stay locked into GVCs at the bottom of the so called ‘Smile Curve’, in particular as in view of the intensive competition at the fabrication level in the context of the ‘servitization’ of manufacturing⁴⁸⁷, the add-

ed value has shifted to pre-fabrication and post-fabrication services. (see Figure 3.1.).⁴⁸⁸ The future development of user-based manufacturing (or cloud-manufacturing) and 3-D printing will likely accentuate this trend.

Figure 3.1.: The ‘Smile curve’

Source: Baldwin/Evenett (2012)⁴⁸⁹

Methodologically, the firm-level analysis draws strongly on institutional economics and works on relational contracting especially by *Oliver Williamson* and *Ian MacNeil* to echo an awareness for the plurality of chain structures. This orientation allowed an easier reception among legal scholars of contract and business law who have equally explored those authors⁴⁹⁰ – which, up until today, is one of only a few legal discourses that has stepped up to take GVCs seriously as a conceptual and economic policy challenge.⁴⁹¹

3.2.2.2. Dual Role of Private Governance in the GVC framework

Private governance plays a dual role in the GVC framework: it provides the instruments, legal and other, that animate the value chain and connect chain actors with each other in order to accomplish an integrated production process. Such governance regimes can encompass contracts but also business routines and practices, logistics, reporting documents and practices, as well as reputation and trust.⁴⁹² Functionally, private governance

regimes combine elements of legislative, administrative and adjudicative power.⁴⁹³ Substantively, private governance regimes set standards of cooperation, stipulate information rights, allow for on-site visits and reporting duties, transfer IP and other assets and generally allocate risks related to incidents along the chain. Besides this role in setting free the economic rationality of production, private governance has increasingly been used to make up for deficits of public regulation in the fields of product safety, environmental protection, labour rights and recently data protection. The integration of such concerns into pre-existing and novel instruments of private governance has not been without frictions and the effectiveness of a private implementation of public goals has so far been controversial.⁴⁹⁴ Despite of this skepticism, private governance today pertains both to the animating and the regulating dimension of private instruments within global value chains.

*Gereffi et al.*⁴⁹⁵, in their leading typology of governance modes of global value chains, select three essential variables to describe governance and change of global value chains: (1) the complexity of transactions, (2) the ability to codify transactions, (3) the capabilities in the supply-base. The typology presented a crucial interest by going beyond the *Coase*'ian dichotomy between firm/market and highlighting network forms of governance in between. Drawing on institutional economics and production network theories, the typology asked how coordination across a geographically dispersed network of suppliers was even possible. It found institutional innovation combining the flexibility of the free market and the trust and stability generated through long-term contractual relations. It is concerned with explaining the modularity of a physical good through patterns of industrial organization and trade. This lies at the heart of the input-output-heuristic used to describe chain governance: Different resources such as technology, material and labour inputs are through of as existing independently of each other and being brought together, processed, assembled, marketed and distributed. At the inter-firm level, coordination can be assured through factors such as asset specificity (mutual dependence), repeat transactions, reputation and social norms.

Based on this, *Gereffi et al.* distinguish between five analytical (not empirical) types of governance: Markets – modular value chains – relational value chains – captive value chains – hierarchy. For each of these types, they inquire into the conditions under which each of them seems likely to arise and conclude by identifying three principal parameters: (1) the complexity of information and knowledge transfer necessary for a particular transaction, (2) the degree of codifiability of this information and knowledge, and (3) the capabilities of the supplier base in relation to the requirements of the transaction.⁴⁹⁶ (see Table 3.1.)

Table 3.1: Governance types in GVC

Governance type	Complexity of transactions	Ability to codify transactions	Capabilities in the supply-base	Degree of explicit coordination and power asymmetry
Market	Low	High	High	Low
Modular	High	High	High	
Relational	High	Low	High	
Captive	High	High	Low	
Hierarchy	High	Low	Low	High

Source: Gereffi et al.⁴⁹⁷ (2005)

In **modular value chains**, buyer and supplier relationships are governed comparably to a price-based, market-type structure, while both actors share knowledge of common standards. Such chains are characterized by high complexity of information but likewise high codifiability. This allows buyers to find a capable supply base even for complex requirements, as eg in a turnkey supply business model that accomplishes demanding production without particular oversight.

Relational value chains arise where shared standards and thus easy codifiability do not exist. Hence, quality commands require closer cooperation between buyer and seller based on mutual trust, information exchange, reputation and particular contractual regimes. Typically, relational value chains can be found in the development of new products, such as prototypes.

Captive value chains can be found when supplier capabilities are relatively low while the ability to codify and also the complexity of the production process are high. Here, the supplier needs to cooperate with the buyer and cannot easily switch to different markets.

Based on this matrix, it becomes possible to identify how common dynamics with respect to one or several of these parameters (eg an increase in the complexity of transactions) impact on the governance structure of the chain⁴⁹⁸:

3.2.2.3. Explanatory Potential of the GVC approach

The GVC framework is a powerful methodology to engage in a mapping exercise of the respective actors who cooperate in a particular value chain and to describe the power relationships between them. In particular, the GVC framework has been widely used to investigate the parameters which impact upon issues of participation, rent distribution, and development. Also, it has identified how innovative types of normativity and private

ordering, from informal to more formalized, are used to organize coordination.⁴⁹⁹ As an example, the GVC framework has early highlighted the way in which technical and process standards are used by lead firms to reduce complexity of the chain.⁵⁰⁰ Unlike market-type relations, that are essentially governed by price information, such standards codify non-price information to organize coordination. Somewhat analogously, in the field of digital value chains, means of cooperation are introduced into the code design as technical infrastructure of platforms and communicative interfaces between systems (eg application programming interfaces, APIs). At the same time, the firm-level approach and its de-territorialization of concepts of production did not, however, remain uncontested within GVC analysis itself, where scholars claimed a stronger combination of micro- and macro-level factors and most crucially broader entry points of political economy.⁵⁰¹

3.2.2.4. Defining the right unit of analysis for public policy purposes: Digital Value Chains, Platforms, Ecosystems

When seeking to apply the GVC framework to digital value chains, both a promising explanatory potential as well as some obvious limitations become clear – alongside a series of less obvious and still to be detected limitations.

Interestingly, the shift from “digital value chains” to “ecosystems” seems to correlate somehow with an internal debate in the value chain literature in which some suggested a concept of “global production networks”⁵⁰² to replace the “value chain” concept. In advocating this novel concept, scholars sought to express more accurately (1.) the nodal, not linear agency structures in a production process (rather “network”, then “chain”) and (2.) link the analysis of governance modes to studies on governmentality and shared normative practices. The term of “ecosystem” is used to depict highly dynamic types of “entangled alliances” between companies irrespective of regional and sectoral attribution, characterized by both path dependency and high volatility.⁵⁰³ Digital ecosystems describe a constellation of products, organizations and people across industry clusters which are connected through a digital platform. Ecosystems sell holistic “outcomes”, such as access to safe mobility, rather than fragmented products, such as automotive, service plans and insurances.

At the same time, the GVC framework can only be transposed with a cautious awareness for some of its limitations. Firstly, the typology by Gereffi *et al.* corresponds to a

firm-level analysis, leaving both macro-level impacts as well as interpersonal preconditions such as inculturation practices of supply chain managers outside of the picture. Secondly, and even more crucially, the role of data is a significant lacuna, not only in explaining digital value chains but growingly also for data-driven manufacturing. Data (access) becomes the currency of power along the chain and decisive for the distribution of rents.

In fertilizing the GVC framework for digital value chains, a few adjustments appear crucial:

- (1) Platforms have both their business model and their very operating logic embodied in private governance structures. Hence, the role of private governance is different and even more crucial than in the world of physical production. In physical production, the value chain becomes an instrument to optimize profitability in the production of a given good and private governance is used to orchestrate production resources to realize benefits from outsourcing. Under the lean production paradigm, value chains can relatively easily be subdivided into sequences or delivery steps which string together. In digital value chains, private governance only brings the platform operability into being, it *constitutes* the product, rather than merely *optimizing* its production.
- (2) As a consequence, the fragmentation of product value chains into different “tiers” finds no correspondence in the digital value chain. Instead of sequences of production (“tracing a commodity”), the data value chain can be modelled around steps of data treatment: data acquisition, analysis, curation, storage and usage.⁵⁰⁴ Once a platform is in place, these steps coincide and therefor call for a modelling of the business context and relationships between key stakeholders that is not premised on tracing a single information package (as in physical production).
- (3) As a consequence, in the field of platforms, divisions between classical business sectors seem much more fluid, essentially because the usability of data crisscrosses these sectoral boundaries. Platform business models are not geared towards a stable final product (eg an automobile), but dynamic in themselves, easily moving sectors and adding new ones to the portfolio (eg e-commerce platform engaging also in financial services). This is significant from a value chain perspective, which cannot be centered around a final product (or “core competence”) but has to account for the openness or elusiveness of the “final product” through focusing on process and capabilities. While in physical value chains, the underlying dynamic to increase rent capture is “upgrading” (=attempt of a value chain actor to „move up the chain” towards more lucrative segments of the production process), “upgrading” in digital value chains seems to imply to search for activities for which one’s data set is most lucrative.⁵⁰⁵ Rather than “moving up a *given* chain” this means to *expand* the chain as such. In fact, it seems that platforms which have reached a

504 See E. Curry, The Big Data Value Chain: Definitions, Concepts, and Theoretical Approaches, in: J. Cavanillas/E. Curry/W. Wahlster (eds), *New Horizons for a Data-Driven Economy*, 2016, 29, 32.

505 P. Evans/A. Gawer, *The Rise of the Platform Enterprise. A Global Survey*, The Center for Global Enterprise, 2016, at 17.

significant market share in one sector (“bottleneck”) aim at becoming more integrated across other business sectors. As a result of big data as animating logic of platform businesses, an expansion in user numbers (rather than a focus on “premium” users) seems the preferred trajectory of most platforms. Under big data, size not only allows to do similar things on a larger scale, but allows to engage in activities that would be inaccessible on the basis of a smaller data set. Hence, a “lifecycle approach” to platforms which includes phases of growth, financialization and consolidation provides a helpful heuristic.

- (4) For the most part, private law scholarship has focused on the contractual relation between platform and end-user and not adopted an ecosystem perspective⁵⁰⁶ (similarly, in physical production, contract law scholarship has focused on individual contractual relations and neglected the systemic context of the chain). This view needs to be expanded in a two-fold sense: (a) by adopting an ecosystem perspective that encompasses the diverse set of economically dependent actors; (b) by inquiring not solely formal legal relations, but also extra-legal incentives and rules of cooperation, as exemplified by prior work on contract governance.⁵⁰⁷ This heuristic of private governance can then, in a second step, inform a range of legal policies, including competition law, but also data protection, liability, tax, corporate, labour and others.

3.3. Challenging the ‘natural order’ explanation: the regulating role of digital platforms

The development of digital platforms controlling in some cases quite wide ecosystems constitutes one of the characteristics of competitive game in the digital age⁵⁰⁸. These ecosystems and the underlying relations between the various members are quite complex and link different business actors that are present in various markets with different categories of users. Some of these interactions have been theorised as taking place in multi-sided markets, the concept aiming to translate, in market terms, the presence of feedback loops between different users and business actors that generate value through the operation of non-linear complementarities. Hence, these multi-sided markets do not form a natural order that pre-exists the emergence of digital platforms. They result from the building of a specific digital platform business, rather than being linked to a technologically determined outcome (according to the traditional view of economic organisations as having a productive function) or to the nature of the transaction (according to the transaction costs economics view of the firm). Multi-sidedness forms an

506 See eg C. Petersen/V. Ulfbeck/O. Hansen, *Platforms as Private Governance Systems – The Example of Airbnb*, NJCL 2018, 39 et seqq.

507 For a comprehensive state-of-the-art overview cf S. Grundmann/F. Möslin/K. Riesenhuber (eds), *Contract Governance. Dimensions in Law and Interdisciplinary Research*, 2015.

508 See our discussion in Chapter 4.

endogenous choice, which makes some authors to observe that it is better ‘to discuss two-sided “strategies” rather than two-sided “markets”⁵⁰⁹.

If one takes this seriously, the focus should turn from the ‘nature’ of the market to business strategy. Building a successful digital platform business involves various steps: (i) choose the different market sides the platform will be active, (ii) solve the chicken-or-egg problem involving a choice to be made as to which side of the market will subsidize another, (iii) design a business model, and (iv) establish and enforce ecosystem rules⁵¹⁰. We focus here on the fourth issue, which relates more closely to the governance by the digital platforms of their ecosystem of complementors.

Digital platforms do not only compete with each other, but they also compete sometimes with their complementors. By developing platform rules that regulate their interactions with complementors, and also the interaction between complementors, digital platforms are able to manage competition. This provides them control over the market and enables long-term planning. This was traditionally the function of the so called ‘technostructure’ in the conglomerate forms of organisation that emerged in the 1960s expanding in different economic sectors⁵¹¹. The difference here is that this control is not exercised on the different parts of an integrated company or through longer-term supplier and labour contracts, but on value chains formed by formally independent companies present in adjacent markets (complements) to the market on which the digital platform or the system integrator holds a pre-eminent position. This form of managed competition is not only regulated by contract, but also by ‘uncontract’ and technological forms of governance (code).

The development of the digital economy rests on the convergence of the telecommunications value chain with those developed for private and enterprise computing⁵¹². While until the mid-2000s the telecommunications industry used circuit switched (CS) technology and the computer industry packet switched technology (PS), the two forming two separate value chains, the push towards cheaper and more efficient integrated circuits because of progress in the semi-conductors industry and the development of multichip packaging solutions combining several functions into one system led to a co-evolution of the worlds of computing and mobile telephony. What emerged from this gradual convergence are technical platforms, combining together hardware and software along a common architecture based on a three-layer model: an access network layer (for the time being different for telecommunications and computing), a core network layer and a service layer⁵¹³. As Mulligan explains, the function of the platform “is to hide system complexity from those third parties that wish to use the functionality but do not need to implement it themselves”⁵¹⁴. This is achieved by creating applications on top of an operating system via a set of publicly available interfaces that are also known as Application

Programming Interfaces (APIs). This is a set of standalone instructions, routines, protocols, and tools for building software applications indicating how software components should interact for specific functionalities. Conceived as modules, APIs help developers to make calls for code reuse across many different programs even if the code was initially created for a particular problem. This came to prominence after the decision of IBM in 1968 to price its software and services separately from its hardware, a sort of unbundling, among other reasons also in order to pre-empt antitrust enforcement, the company being under investigation since 1967⁵¹⁵. This modular approach also helps the easier and speedier creation of applications by third-party developers and allow them to hook together different parts of the system (e.g. hardware, peripherals and software)⁵¹⁶. As the architecture of networks becomes more software-based than hardware-based, the interface definition also moves from hardware to software and consists in the “handling of ‘bits’” (a small piece of information)⁵¹⁷. Developers do not need to know the details of the interaction of the hardware with the software. The technical platform handles this on their behalf through the APIs. Vertical connection between nodes on these platforms enabled by APIs allow for the automatic flow of information between the different actors in the value chain.

To the extent that the system relies on open interfaces, the boundaries of these value chains are not delineated by the limits of the organisation, or contractual arrangements with suppliers and customers, but remain flexible, the length of the value chain being determined by the degree of the openness of APIs. Mulligan coins the term ‘participatory value chain’ to show how open interfaces and open APIs reinforce the role of the end-user consumer and transform digital value chains from producer-driven to buyer-driven. Indeed, “(i)n actual fact, each time an end-user selects a specific service, they are activating different parts of different value chains”⁵¹⁸.

These interfaces allowing the different parts of the platform to work produce both demand side economies of scale, as end-users value compatibility *within* the same platform in order to be able to use different applications, and supply-side economies of scale, which result from the need to ensure interoperability *across* different technical platforms⁵¹⁹. The interfaces connecting different parts of a platform may therefore be horizontal (allowing the constitution of platforms by several different companies present in various segments of the industrial structure), or vertical (connecting the service layer with core networks and used to develop complementary products and services)⁵²⁰.

Open interfaces could thus be considered as substitutes to formal contracting. They offer the ‘glue’ that holds the digital value chain together, “(s)ervices built on open APIs essentially function(ing) as a string of bargaining relationships between the different

actors involved in the service (and any competing service)”⁵²¹. They are also at the origin of new markets between companies seeking to find flexible ways to handle dynamically the uncertainty of technological change by sharing small amounts of data on an ongoing basis, between themselves and with the developers, without this requiring them to contracts and thus incur transaction costs. Technology and code are used, instead of contracts, in order to establish connectivity between the different components (and companies) forming the platform and between the complementors and the platform⁵²². As Mulligan explains, APIs ‘allow for the knowledge contained within different technical systems to become unembedded, creating the possibility for many different economic entities to combine and share their data’, meaning that ‘knowledge is no longer tied to one digital system’⁵²³. This informal nature of these arrangements may nevertheless become source of power for ‘system integrators’, such as digital platforms. These finish by co-ordinating a vast amount of economic activity ‘outside the boundaries of the legal entity in terms of ownership’⁵²⁴ but also outside formal contractual ties.

The convergence of computing and telecommunications, in recent years, and the broader process of convergence with Artificial Intelligence and the Internet of Things (IoT) has profound implications on the constitution of digital value chains. The emerging information-driven value chain may trigger a process of competition and concentration across industrial boundaries. Telecommunication companies/mobile network platforms will enter into ‘competitive clashes’ with computing platforms, cloud computing platforms, mobile broadband platforms etc., each of them competing in order to become the new system’s integrator⁵²⁵. The industrial structure that will emerge will very much result from the way each of these actors will handle APIs and in particular the process of standardisation in order to handle the technical complexity of their interaction. The process is different in the communications industry in comparison to the computing industry. The former traditionally followed a model of cooperative standardisation with the development of industry fora to establish ground rules for global standards. In contrast, the latter followed a *de facto* standardisation approach enabling some companies whose proprietary technology became popular to have this accepted as an industry standard, thus raising the risks of market tipping.

To the extent that APIs allow a platform to be used by more people and companies, thus intensifying its network effects, a strategy of open APIs may become a significant source of market value, as a rapidly growing market share attracts financial investors. The role of system integrator offers, in particular, important opportunities for surplus value that would be generated not so much by a better use of the company’s assets mainly but by the exploitation of the business ecosystem relying on the infrastructure of the specific technical platform. Strategies of control over APIs and interfaces therefore provide the

foundations of the private governance systems that emerge in order to organise the process of value extraction.

3.4. A Typology of private governance systems: a theoretical perspective

The *Gereffi* framework establishes a typology of governance modes, which in essence concerns the relations between the lead firm and its principal, ie first/second tier suppliers. “Governance” here denotes the bundle of instruments, both legal and other, that allow a lead firm to coordinate its chain. Such tools overcome in part the boundaries of privity of contract and have been described as “contract boundary-spanning”⁵²⁶ in legal terminology. While the emergence of such tools seems intuitive from a perspective of institutional economics, the type of governance can be challenged on normative grounds: Does a lead firm’s governance type provide for sufficient leverage to implement sustainability requirements along the chain? Who can challenge the adequacy of a governance regime that reaches beyond a bilateral contract? Who (and how) ought to evaluate the effectiveness of a governance regime?

For the reasons outlined above, the typology by *Gereffi* cannot be transposed one-by-one to digital value chains and even more so to ecosystems, since it presupposes a segmented linearity of physical production which seems misleading in the face of data-driven business models. In other words, even an ecosystem with a strong centralized power locus will not amount to a degree of hierarchical control as imagined in the “hierarchy” model by *Gereffi* and even the most heterarchical ecosystem will not follow mere “market” transactions as in *Gereffi* since the ecosystem’s infrastructure will require coordination beyond mere spot-relations. In addition, both the tools as well as the substantive rules of governance will differ for digital value chains because of a novel incentive and revenue structure (with customers often paying through their data, thereby becoming part of the value generating process). Furthermore, the centrality of technology and code offers an additional venue to implement governance by design, such as through the steering power of search algorithms, customer reviews or transparency rules regarding transactional data. Ultimately, the stakes of governance are recalibrated when digital platforms become gatekeepers for entire industries or social practices (such as messaging or online dating), shifting the relevant mechanisms of control from individual clauses through contract law and unfair terms to business and governance models through competition law more broadly.⁵²⁷

This makes it ever more crucial to not identify governance with formal legal rules but to think of governance as the interplay between positive rules (of varying degree of formality) and spaces of “ungovernance”, ie spaces which appeal to and incentivise actors in an ecosystem who might be insensitive to strict governance rules. Generally speaking, three levels of governance can be distinguished: (1) **contractual governance** (as mani-

526 Cf J. Salminen, Contract-Boundary-Spanning Governance Mechanisms: Conceptualizing Fragmented and Globalized Production as Collectively Governed Entities, *Indiana Journal of Global Legal Studies* 23 (2016), 709-742.

527 See eg most recently T. Höppner/P. Westerhoff/J. Weber, Taking a bite at the Apple: Ensuring a level-playing-field for competition on app stores (May 13, 2019), <http://dx.doi.org/10.2139/ssrn.3394773>.

festated in specific clauses, such as on exclusivity, royalties or termination); (2) **soft and informal governance** (including aspects of community-building, standards of behaviour, perks and reputational governance) as well as (3) **technological governance** (as imposed through the technical interface of the platform, implemented eg through the control of APIs, algorithms, patents, etc.).

Overall, a governance typology for ecosystem governance inspired by Gereffi could be situated on a continuum ranging from “participatory/collaborative” via “relational governance” to more “captive/intrusive” governance. Those types will differ with respect to the following features that appear as crucial and allow to base a preliminary typology upon them: (1) entry and exit barriers of the ecosystem; (2) degree of formality and transparency of governance instruments and conditions, (3) degree of customizability of the governance model and the platform use; (4) price model; (5) functionality of dispute mechanisms.

	Entry/exit barriers (performance standards, community-oriented regulation/lock-in effect, switching costs)	Transparency of governance instruments and conditions	Degree of formality of cooperation/degree of appeal to extra-legal norms (trust, reputation)	Customizability	Price model	Function of dispute mechanism
Participatory/collaborative governance	Low	Transparent	Informal	Low	Finance	Learning
Relational governance	↓	↓	↓	↓	↓	↓
Captive/intrusive governance	High	opaque	Formal	High	Data	Deterrence

This typology will be tested against a series of case-studies of platforms of different nature and from different business sectors.⁵²⁸ The studies include *Google/Alphabet* (search and internet services), *Amazon* (online retail and cloud computing), *Airbnb* (short-term rentals), *Tinder* (online dating) as well as *Sberbank* (financial services). The guiding question for these studies was to understand how the governance regime (contractual, soft/informal and technological) of an ecosystem affects the allocation of value and how it is co-shaped through the functionality of the ecosystem and its regulatory environment, including eg platform liability rules.

528 For a helpful categorisation cf P. Evans/A. Gawer, *The Rise of the Platform Enterprise. A Global Survey*, The Center for Global Enterprise, 2016: “transaction”, “innovation”, “integrated”, “investment”.

3.5. Beyond the ‘natural order’ rhetoric: a (legal/technology) institutional perspective

3.5.1. Contractual governance – Legal institutionalism

With respect to digital platforms, even more so than in bricks-and-mortar economy, market dynamics and characteristics can no longer be regarded as stable, pre-existent and emanation of a natural order. Such an essentialist view has recently faced criticism by approaches of a “legal institutionalism” which have identified certain institutions as backbone and central characteristic of capitalism and highlighted the role of law in establishing and maintaining them.⁵²⁹ Institutions mark the settings of human interaction which are governed by respective operating rules. Institutions, here, appear as “part and parcel of any mode of production”⁵³⁰, they shape, rather than merely follow, modes of production. For instance, behind technology as driving force of economic innovation, legal institutionalism points out that without property rights, finance and other legal parameters, technological innovations are unlikely to have emerged.

In this, “legal institutionalism” builds on previous institutional accounts of law (C. Schmitt, M. Hauriou, S. Romano, N. MacCormick) and both transposes and profoundly sharpens the institutional economics’ insights into law.⁵³¹ Unlike *Williamson*⁵³², who – drawing on *Coase*⁵³³ – established the role of law in building economic institutions but saw law and particularly private ordering as essentially serving efficiency between firms and markets, “legal institutionalists” claim a more holistic understanding of the law and its basic concepts as social and economic institutions. While taking private ordering in its current pervasiveness and also practical appeal serious, “legal institutionalists” likewise reflect on the power structure implicated in private ordering.⁵³⁴ Legal rules are evaluated not solely in their influence on rational acting individuals, but in their institutional effects, namely those effects that under realistic assumptions arise from the aggregate use of the particular rights and entitlements that a legal rule confers. In this light, for instance, the circulation of knowledge in society crucially depends on the design of institutions, among them legal institutions such as competition law.⁵³⁵

A central tenet of these approaches that proves valuable for the digital era is to conceive of the legal status quo as one out of many possibilities of legal design, realized to some

535 Cf eg D. Wielsch, Private Governance of Knowledge: Societally-Crafted Intellectual Properties Regimes, *Indiana Journal of Global Legal Studies* 20 (2013), 907 – 940.

degree by choice and by path dependency. Hence, when confronted with novel social or economic phenomena, their current emanation needs to be thought of as legally constructed and potentially amendable by legal means. As an example, with regard to the governance of global value chains, the “Research Manifesto” by the “IGLP Working Group on Law and Global Production” has argued that

“law is more than an ‘external’ or contextual factor shaping the strategic decision-making of firms ‘inside’ GVCs. Rather, we argue that law resides at the heart of the GVC phenomenon—it is the vehicle through which value is generated, captured and distributed within and between organisational and jurisdictional domains, and diverse and geographically disparate business operations are coordinated and governed.”⁵³⁶

The contractual relations under a given ecosystem depend on its functionality. Take the example of a matchmaking platform, such as Amazon (retail), Airbnb (short-term rentals) or Tinder (dating): Both the “supplier” and the “client” (or in the case of Tinder: both users) are bound to the platform by standard contract terms (boilerplate). Those terms stipulate the rights and duties of the platform and the respective participant, formulate standards of behaviour for the community, including ways of exiting and sanctions. With the platform itself being a counterparty in these contracts, they establish the infrastructure required to realize the business plan (“vision”) of the platform on a “take-it-or-leave-it” basis. What appears as community standards is *de facto* put in place through the central regulatory capacity of the platform.⁵³⁷ The more “community-life” a platform can generate, the higher its consumer loyalty and also its data set (through reviews, social tracking, usage rates) will be.

The contract concluded between supplier and client is itself largely regulated or co-regulated by the platform.⁵³⁸ Both supplier and client are provided with a fully-fledged regulatory framework that their transaction is based upon, including primary rules, rules of interpretation and oftentimes dispute resolution. Typically, these rules serve as default rules and can be customized in some respect, whilst not in others. This entails a risk of abuse of a dominant position of a platform which can steer – either through binding rules or through the effects of defaults – the contracting member’s behaviour, eg through beneficial pricing or an allocation of risks that primarily serves the platform (eg by attracting more members on the demand/supply side).

The role of contract governance is crucial in part because classical points of intervention of national legislation are not effective with regard to online platforms, eg because they (try to) circumvent guarantees of labour law (*Uber*) or tax law (*Airbnb*). The significance of private governance in online platforms has been endorsed in the 2016 Communication on Online Platforms by the European Commission and seems unlikely to change very soon. In this Communication, the Commission stated that “principles-based self-

538 Cf M. Grochowski, Spontaneous Order in the Sharing Economy? A Research Agenda, *Zeszyt* 49 (2018), 75 et seqq.

regulatory/co-regulatory measures, including industry tools for ensuring application of legal requirements and appropriate monitoring mechanisms, can play a role⁵³⁹ in the future regulatory framework. While the majority of rules within terms & conditions are global in reach, it has become common to add national specifics which reflect regulatory environment, national case-law and rules on unconscionability.⁵⁴⁰

The mechanisms of legal control of private governance depend on the nature of the rules. While in B2C contracts, Europe and other jurisdictions review clauses under a criterion of fairness and many jurisdictions contain sectoral rules of privacy protection, in B2B contracts only very limited reasons for unconscionability exist. At the same time, there are increasing similarities between types of clauses used by platforms which are perceived as unfair by other actors in the ecosystem. A survey conducted by the European Commission⁵⁴¹ found that in B2B relationships, contract clauses from standard T&Cs were deemed problematic by businesses insofar as (1) rules cannot be negotiated; (2) platforms often reserve the right to unilaterally change their T&Cs; (3) clauses require a 'bundling' of subscriptions to various services of the platform, including auxiliary services, and may prescribe proprietary payment systems, data clouds or communication channels; (4) platforms such as travel agencies or hotel booking sites use 'parity clauses' which impose a price at least as low as offered through other distribution channels; (5) rules restrict the access to and/or use of data, thereby hindering a switch of platforms. Cross-cutting issues were unclear termination and suspension conditions and procedures (as illustrated by the case-study on Amazon) and generally complex and vague terms.

Given the recurrence of typical clauses across platforms, recent initiatives to formulate model clauses for digital platforms may have promising leverage. Those include the European Law Institute's "Discussion Draft of a Directive on Online Intermediary Platforms"⁵⁴² as well as the EU Proposal for a Regulation on promoting fairness and transparency for business users of online intermediation services (P2B Regulation).⁵⁴³ Importantly, model clauses will typically (although not necessarily) be limited to a formal, contractual level of governance and leave more informal, social and technological levels unaffected. This is a strong argument in favour of mobilising competition law and its particular sensitivity towards filigree emanations of economic power for digital platforms, alongside more conventional and long-standing instances of contract law and consumer protection.

543 COM(2018) 238 final.

3.5.2. Contract automation under big data: The “uncontract” (Zuboff)

Theories and practices of contract governance have relied so far on governing other individuals or entities through mechanisms of control, incentives, sanctions and rewards. Contracts, and even more so the contractual regime that binds contract together, serve to reduce uncertainty about the future behaviour of others, by formulating expected standards of behaviour coupled with varied mechanisms to lend them effectivity. Novel, IT-based forms of interaction such as through blockchains challenge this view of contracting. Here, the personal dimension of interaction is increasingly supplanted by technology, allowing to predict behaviour of others through data, not the “contract” rules, and “enforcing” them automatically by technological means. Take, for instance, the “enforcement” of a decision by the dispute body of ICANN (UDRP)⁵⁴⁴ through the deletion of a domain or the real-time adjustment of car insurance premiums based on the insurance holder’s driving style. Zuboff⁵⁴⁵ has termed such phenomena that subvert the essence of contracting an “uncontract”, rather than calling them a new form as contracting. As she describes it:

‘The uncontract is not a space of contractual relations but rather a unilateral execution that makes those relations unnecessary. The uncontract desocializes the contract, manufacturing certainty through the substitution of automated procedures for promises, dialogue, shared meaning, problem solving, dispute resolution, and trust: the expressions of solidarity and human agency that have been gradually institutionalized in the notion of “contract” over the course of millennia. The uncontract bypasses all that social work in favor of compulsion, and it does so for the sake of more-lucrative prediction products that approximate observation and therefore guarantee outcomes’.

Hence, the bilateralism of contracts – which had, to be sure, already become a fiction in many instances, but still underpins the theories and doctrines of contract – ultimately loses all its ground. Instead of a – however fictitious – “meeting of the minds”, neither “minds” nor their “meeting” seems necessary in case of “uncontracts” that are “unprecedented in their ability to impose unilateral power”⁵⁴⁶ because of technological or economic dependence. In other words, contract governance needs to reflect that not only the whole lifecycle of contracts is subject to digitalization⁵⁴⁷, but that basic elements of contracts are absorbed within technological mechanisms of compliance, algorithmic governance or governance by design. Further examples can be drawn from the broad field of smart contracts, eg in an emerging “lex cryptographia”⁵⁴⁸.

544 <https://www.icann.org>.

545 S. Zuboff, *The Age of Surveillance Capitalism*, 2019, 208 et seqq.

546 S. Zuboff, *The Age of Surveillance Capitalism*, 2019, 314.

547 S. Grundmann/P. Hacker, *Digital Technology as a Challenge to European Contract Law – From the Existing to the Future Architecture*, *European Review of Contract Law* 13 (2017), 255-293.

548 Cf eg A. Wright/P. De Filippi, *Decentralized Blockchain Technology and the Rise of Lex Cryptographia* (March 10, 2015), available at <http://dx.doi.org/10.2139/ssrn.2580664>.

Such practices for the most part fly under the radar of control of contract and consumer protection law. “Uncontracts” are no isolated parts of T&Cs that can easily be struck down as in a blue-pencil-test, but (a) become integral parts of the platform service itself that (b) don’t present themselves as identifiable contractual device any longer. Instead of putting each and every one of such “uncontracts” under scrutiny individually, regulatory responses need to address them at a more abstract, overarching level. Towards this, public governance, most notably through competition law can determine permissible practices, while standards of rule of law can establish procedural guarantees vis-à-vis technological processes. The current awakening of competition law for the digital era illustrates that perceptions of technology as “law-less spaces” – as was misleadingly assumed in the early days of the Internet – have been overcome. Competition law placed within a broader, inclusive agenda can formulate transnationally operative “constitutional” rules for digital platforms and markets that subject them to the rule of law.

Such meta-level approach can ultimately also be embedded in the private governance of platforms themselves and add a self-reflexive element to their operations. One can think of combinations between substantive (eg ethics codes in venture capital), procedural (platform-related dispute mechanism) or institutional (eg Ombudsman) rules and instruments. Examples would be the content screening undertaken by Facebook partly on its own account and partly under the influence of national legislation, such as the pioneering German *Netzwerkdurchsetzungsgesetz* (NetzDG).⁵⁴⁹ This law requires commercial social networks to establish transparent procedures for dealing with complaints about illegal content such as hate speech. Furthermore, social networks are required to (1) check complaints immediately; (2) delete „obviously illegal” content within 24 hours and (3) delete any illegal content within seven days after checking and block access to it. Documentations regarding each complaint and content need to be stored for at least ten weeks.

Interestingly, the regulatory debate around digital platforms converges strongly on this point with the debate around a fairer or more sustainable private governance of global value chains of production. After more than a decade of relatively toothless experimentalism with various instruments of Corporate Social Responsibility (CSR), a reinvigorated interest in and engagement with possible legislative interventions can be observed.⁵⁵⁰ These depart in a way from mere market-based forms of regulation through markets for ethical standards and reputational sanctions, while at the same time acknowledging the challenge of complexity which requires a certain degree of participation and wilful compliance by lead firms. The regulatory debate around GVCs certainly shows that regardless of the legal origin of regulatory initiatives – be it in legislation, transnational standards such as by the ILO or corporate codes of conduct – only those regulations can be effective that make a difference in the private governance regime of a chain. Likewise, for digital platforms and ecosystems, different pathways of regulation exist, but

549 https://www.bmju.de/SharedDocs/Gesetzgebungsverfahren/Dokumente/NetzDG_engl.pdf?__blob=publicationFile&v=2; for a comprehensive overview of legal issues cf M. Eifert/Th. Gostomzyk (eds), *Netzwerkrecht. Die Zukunft des NetzDG und seine Folgen für die Netzwerkkommunikation*, 2018.

550 Eg G. Sarfaty, *Shining Light on Global Supply Chains*, *Harvard International Law Journal* 56 (2015), 419.

again, a promising objective is to implement fairness *within* the very private governance of the respective platforms and ecosystems.

3.6. Drawing on the empirical evidence: a bestiary of governance tools in digital platforms and ecosystems

Despite the wide array of sectors in which the studied platforms and ecosystems are active, there are significant similarities that emerge as patterns of governance.

To begin with, it is noticeable how much the factors of size, experience, and establishment impact upon the governance regime. Typically, start-ups will follow a more participatory/collaborative scheme while the global market leaders deploy their enhanced bargaining power through more captive/intrusive governance models. Hence, it is essential to include a genealogical element of platform growth into the analysis to be able to engage with changes of business strategy (such as in pricing models) that occur across phases of growth. This gap is even bigger between platforms which are genuinely digital from the start and the incumbent firms of the manufacturing and asset economy which growingly seek to include platform elements to develop their business model.

Secondly, it is worthwhile to distinguish between (a) relationships between the platform and the businesses (P2B) forming part of their ecosystem and (b) the relationships between the platform and their customers/consumers (P2C). Both relations are ruled by an assemblage of codified, formal as well as informal rules and practices as well as technological infrastructure. Yet, they centre around different legal matters of concern. While P2B relations face little regulatory constraints outside of competition law, P2C relations are more thoroughly put under scrutiny by consumer and privacy law.

3.6.1. Patterns of governance in P2B relations

3.6.1.1. Translating business models into governance patterns

As regards P2B relations, the case studies all pertain to platforms that are constitutive for their respective key market(s) segment(s). Terms of Service (T&Cs) here animate a technology-based, digital network that ensures a steady supply of platforms with infrastructure, data and clients beyond corporate ownership or hierarchical steering. The private governance regimes are designed to enable agility in terms of the business model by placing the burdens of investment in specialization in classical business sectors on the platform's contractors (eg the Airbnb hosts, the Marketplace sellers, the Uber drivers, the Android developers) while allowing the platform to proceed to cross-sectoral investments that form an ecosystem.⁵⁵¹

The contractual governance regimes of P2B relations:

⁵⁵¹ Cf <https://medium.com/@heckerhut/modes-of-contractual-governance-in-an-on-demand-service-economy-1833629f379b>.

- (a) create loyalty to the platform and consolidate it as a privileged channel for marketization of the respective goods and services. Towards this, terms set certain entry barriers by asking for an alignment with platform-specific ways of presenting one's business, demand price parity, sometimes even exclusivity, the right to use IP protected material of the business⁵⁵² and the subscription to further but not necessarily related services by the platform ('bundling'), each of these also reinforced in the platforms technological design;
- (b) implement dispute mechanisms that are complex and little transparent, thereby fostering non-legal or soft incentives of the parties. For legal claims, arbitration clauses and a waiver of class actions are common. Pre-legal claims are often handled pursuant to internal dispute proceedings that lack fundamental principles of rule of law (provision of grounds, transparency), especially given the sometimes existential stakes for small businesses, as illustrated eg in the Amazon Marketplace suspension appeal procedure.⁵⁵³
- (c) allow for unilateral adjustment⁵⁵⁴ (including on pricing) and termination⁵⁵⁵, thus giving the platform broad discretion of governance and business development opportunities⁵⁵⁶ over the course of the business relationship while creating high lock-in costs and little inter-platform mobility and data transmissibility⁵⁵⁷ for businesses.

552 Cf Yelp Terms of Service (<https://www.yelp.com/static?p=tos>), Sect. 5B: ('We may use Your Content in a number of different ways, including by publicly displaying it, reformatting it, incorporating it into advertisements and other works, creating derivative works from it, promoting it, distributing it, and allowing others to do the same in connection with their own websites and media platforms ("Other Media")').

553 See infra 3.7.2.3.2

554 Cf Airbnb Terms of Service, Sect. 9.5 ('In certain circumstances, Airbnb may decide, in its sole discretion, that it is necessary to cancel a pending or confirmed booking and initiate corresponding refunds and payouts.');

Apple Developer Agreement (<https://developer.apple.com/terms/apple-developer-agreement/Apple-Developer-Agreement-English.pdf>), Sect. 9 ('Amendment, Communication. Apple reserves the right, at its discretion, to modify this Agreement, including any rules and policies at any time.').

555 Amazon Developer Services Agreement (<https://developer.amazon.com/de/support/legal/da>), Art. 9 (**Term and Termination**. We are entitled to terminate this Agreement and your Program account (including access to your Program account) at our discretion with or without advance notice to you.');

Alibaba Cloud International Website Terms of Use (<https://www.alibabacloud.com/help/faq-detail/42417.htm>), Sect. 4 ('Breaches by User. Alibaba Cloud shall have the right at its sole and absolute discretion to remove, modify or reject any content that you submit to, post or display on the Alibaba Cloud Platform which in our sole opinion is unlawful, violates the Terms, or could subject Alibaba Cloud or our affiliates to liability.');

Airbnb Terms of Service, Sect. 15.4 ('Airbnb may immediately, without notice, terminate this Agreement and/or stop providing access to the Airbnb Platform if (i) you have materially breached your obligations under these Terms, the [Payments Terms](#), our [Policies](#) or Standards, (ii) you have violated applicable laws, regulations or third party rights, or (iii) Airbnb believes in good faith that such action is reasonably necessary to protect the personal safety or property of Airbnb, its Members, or third parties (for example in the case of fraudulent behavior of a Member.').

556 Cf Airbnb Terms of Service, Sect. 1.7 ('Airbnb may improve, enhance and modify the Airbnb Platform and introduce new Airbnb Services from time to time.').

557 Cf confidentiality clauses eg in Apple Developer Agreement (<https://developer.apple.com/terms/>), Sect. 4 ('Confidentiality: Except as otherwise set forth herein, you agree that any Apple prerelease software, services, and/or hardware (including related documentation and materials) provided to you as an Apple Developer ("Pre-Release Materials") and any information disclosed by Apple to you in connection with Apple Events will be considered and referred to as "Apple

3.6.1.2. Interplay between contractual, soft and technological layers of governance

The formal contractual layer is the most significant in P2B relations and ensures the stability of the supply relationship. Soft and technological governance fulfill a complementary role, especially when contractual terms are (sometimes deliberately)⁵⁵⁸ vague or not transparent.

A good illustration of soft governance in the use and potential abuse of a gatekeeper position in an ecosystem is provided by Google's policy towards third-party content providers. Many of them make money from advertising on their websites and are thus dependent on the indirect traffic that is generated by referrals from Google's general or specialized search services. Google uses this dependency to encourage agreements that improve their search results and thus raise the advertising revenue. An example of this can be seen in Google's "first click free" policy, which obligated online news providers to make paid articles available for free when they are accessed over Google Search under the threat of removing the articles from the search results otherwise.⁵⁵⁹ Even though Google has given up on this program, they now offer a centralized subscription service called "subscribe with google",⁵⁶⁰ which rewards participating publishers with higher ranks in the search results of users that have subscribed to that specific service.⁵⁶¹ Two general lessons can be drawn from this example. First, it demonstrates how Google will use the economic dependency of businesses to make them enter into agreements that are beneficial for Google, either by threat (in the case of "first click free") or by reward (in the case of "subscribe with google"). Second, it shows the Google has a strong interest in keeping content available through search, as this gives Google the advertising advantages of a content provider, without bearing the risk of actually providing such content itself.

Technological governance essentially occurs as algorithmic governance in the structuring of listings, the suggestion of price-levels, and the design of the communicative space between businesses and their users.

3.6.1.3. Relevant terms: Data transferability, price-setting, suspension of service/membership

The terms and conditions that are the most highly disputed between platforms and businesses concern the fields of entry/exit barriers through data transferability and the

Confidential Information".); Amazon Developer Service Agreement, Sect. 12 ('You will: (a) protect and not disclose information made available by us that is identified as confidential or that reasonably should be considered confidential; (b) use that information only to fulfill your obligations or exercise your rights under this Agreement').

558 Cf Australian Competition and Consumer Commission, Digital Platforms Inquiry, Final Report, 2019 (available at <https://www.accc.gov.au/publications/digital-platforms-inquiry-final-report>), 418-420.

559 <https://www.theguardian.com/technology/2017/oct/02/google-to-ditch-controversial-first-click-free-policy>

560 <https://www.blog.google/outreach-initiatives/google-news-initiative/introducing-subscribe-google/>

561 <https://searchengineland.com/google-news-initiative-kicks-off-subscribe-google-efforts-294624>

protection of distribution channels, furthermore rules on price-setting and remuneration and ultimately the suspension of service.

A particularly illustrative case for the protection of distribution channels is provided by Google Play. Android developers that offer their applications through Google Play are charged a transaction fee of 30% for app and in-app product sales.⁵⁶² There will be no transaction fee charged when applications are offered for free, but developers are obliged to keep products available for free when they were initially offered for free.⁵⁶³ Google tries to bind developers to the Play Store by providing them with development tools that are only made available to them under the condition that they will solely be not be used for the development of applications for other platforms (including non-compatible implementations of Android).⁵⁶⁴ This prevents the developers from multi-homing, i.e. offering their app in several app stores such as the amazon app store. Google furthermore explicitly prohibits the distribution “any product that has a purpose that facilitates the distribution of software applications and games for use on Android devices outside of Google Play.”⁵⁶⁵

3.6.2. Patterns of governance in P2C relations

3.6.2.1. Translating business models into governance patterns

In platform-to-consumer (P2C) relationships, contractual governance:

- (a) serves the purpose of community-building in order to consolidate consumer loyalty and extract value from repeated transactions and activities on and off the platform which generate a data set that platforms aim to merge. The purpose of community-building is realised to a large extent through social norms and default rules and incentives that are implemented through technology, eg through a membership platform, ratings and discounts for returning customers. As regards privacy policies, the question of a permissible combination of data collected through third-party accounts is crucial since it allows for a much more substantive data set than the one based on internal data only. Such cross-platform merger of data takes place ie by linking accounts on a platform with accounts on another, such as connecting a Facebook user page with one’s Airbnb account, or through social plugins (‘Like’ button). In its decision on Facebook, the Bundeskartellamt has incriminated Facebook’s practice of subjecting access to its services to the agreement that user data through other Facebook-owned apps and services would be aggregated.⁵⁶⁶

566 Bundeskartellamt Decision of 6 February 2019, B6-22/16, https://www.bundeskartellamt.de/SharedDocs/Entscheidung/EN/Fallberichte/Missbrauchsaufsicht/2019/B6-22-16.pdf?__blob=publicationFile&v=4.

- (b) generally implements far-reaching privacy rules⁵⁶⁷, while being complaisant on other aspects of the consumer experience (with lenient cancellation rules, a right to withdraw from contracts, return purchased items etc). Compared to offline consumer experience, this produces a consumer-friendly impression which distracts from tight privacy policies that are economically much more significant for platforms' business models. Especially bigger platforms generate high levels of trust and discard consumer concerns regarding a lack of liability or discriminatory pricing through extensive insurance guarantees (eg Airbnb, Uber) and special offers.

3.6.2.2. Interplay between contractual, soft and technological layers of governance

In order to translate the P2C business model into governance patterns, formal contractual rules are not sufficient. Rather, platforms use contractual, soft and technological governance forms for very distinctive respective purposes. The contractual level is used to ensure the provision with data and the limitation of business risks by limiting liability. Consumers are given little opportunity to customize or opt-out of data protection and usage rules.⁵⁶⁸ The incentives for consumers to join—and more importantly actively use—the platform are however set through soft and technological tools. Soft governance here includes the social benefits of joining services that follow a network logic, ie community-building, exchange with peers, access to peer recommendations; others include rewards for extensive usage (such as enhanced user status or discounts), accommodating rules, and targeted publicity.

A particular illustration of informal governance is the bond created by social media, notably Facebook, anchored in user habits that make a membership extremely difficult to break. Correspondingly, the type of power that online platforms exercise vis-à-vis users is less one of market share or 'government-like' size, but has rightly been described as 'subtle Foucauldian modes' of power that are grounded in and modify the very routines and practices of individual lives.⁵⁶⁹

Technological governance finally is used for different purposes compared to P2B relations, namely to standardize user communication and behaviour (especially in order to prevent them to leave or circumvent the platform) and to structure and rank the offers or listings that are displayed to a user.

3.6.2.3. Relevant terms: Legal qualification of the agreement, privacy, and liability

In the contractual terms between platforms and users, three issue areas are most crucial for the platform, namely the determination of the its own legal role through the legal qualification of the agreement, liability, and rules on privacy and data exploitation.

567 For a compelling comparison across platforms cf Australian Competition and Consumer Commission, Digital Platforms Inquiry, Final Report, 2019 (available at <https://www.accc.gov.au/publications/digital-platforms-inquiry-final-report>), p. 380 et seqq.

568 Australian Competition and Consumer Commission, Digital Platforms Inquiry, Final Report, 2019, 427-433.

569 https://newrepublic.com/article/154504/facebook-new-form-power?utm_content=buffer2c632&utm_medium=social&utm_source=twitter.com&utm_campaign=buffer.

Platforms seek to shield themselves from liability from both consumers and businesses through limitation of liability clauses as well as the insistence to provide only matchmaking services without being party to let alone influential in substance on the agreement concluded through the platform (P2C).⁵⁷⁰

Accordingly, platforms use careful wording to express that the main performance is matchmaking, not a substantial service. Yet, the impression generated towards consumers stands in stark contrast to the restriction of liability and the alleviation of the accurateness of the information, ratings etc. For instance, Airbnb denies any responsibility for the quality of its listings, the information and photographs provided or its hosts, even if they are presented as “verified”.⁵⁷¹ At the same time, the matching between strangers for private home rentals hinges largely upon Airbnb’s role as a trust broker. The social expectations created by Airbnb vis-à-vis its own role and the ascription as an intermediary are much more substantial than is reflected in the Terms of Service.

As regards privacy, platforms collect both personalized and non-personalized data. Personalized data is handled with greater caution and restriction; yet, the definition of ‘personalized data’ varies from platform to platform.⁵⁷² A particular matter of concern is the combination of data sets, as powerfully illustrated by the Data Policies of Google⁵⁷³ and Facebook Data Policy⁵⁷⁴ regarding different Facebook Products. Pursuant to its recent merger strategy, Facebook counts among its services today major web services like WhatsApp, Instagram, Facebook Analytics and Ad Reporting. In addition, Facebook collects user data through the ‘Facebook Login’ and ‘Account Kit’, both of which are widely-used tools allowing the login process on third-party websites and apps. Hereby,

570 Cf. Airbnb Terms of Service, Sect. 1.2 („As the provider of the Airbnb Platform, Airbnb does not own, create, sell, resell, provide, control, manage, offer, deliver, or supply any Listings or Host Services, nor is Airbnb an organiser or retailer of travel packages under Directive (EU) 2015/2302. Hosts alone are responsible for their Listings and Host Services. When Members make or accept a booking, they are entering into a contract directly with each other. Airbnb is not and does not become a party to or other participant in any contractual relationship between Members, nor is Airbnb a real estate broker or insurer. Airbnb is not acting as an agent in any capacity for any Member, except as specified in the Payments Terms.”)

571 Airbnb Terms of Service, Sect. 1.3 („While we may help facilitate the resolution of disputes, Airbnb has no control over and does not guarantee (i) the existence, quality, safety, suitability, or legality of any Listings or Host Services, (ii) the truth or accuracy of any Listing descriptions, Ratings, Reviews, or other Member Content ..., or (iii) the performance or conduct of any Member or third party. Airbnb does not endorse any Member, Listing or Host Services. Any references to a Member being “verified” (or similar language) only indicate that the Member has completed a relevant verification or identification process and nothing else. Any such description is not an endorsement, certification or guarantee by Airbnb about any Member, including of the Member’s identity or background or whether the Member is trustworthy, safe or suitable. You should always exercise due diligence and care when deciding whether to stay in an Accommodation, participate in an Experience or Event or use other Host Services, accept a booking request from a Guest, or communicate and interact with other Members, whether online or in person. Verified Images ... are intended only to indicate a photographic representation of a Listing at the time the photograph was taken, and are therefore not an endorsement by Airbnb of any Host or Listing.”)

572 For a comparison cf Australian Competition and Consumer Commission, Digital Platforms Inquiry, Final Report, 2019 (available at <https://www.accc.gov.au/publications/digital-platforms-inquiry-final-report>), p. 409-410.

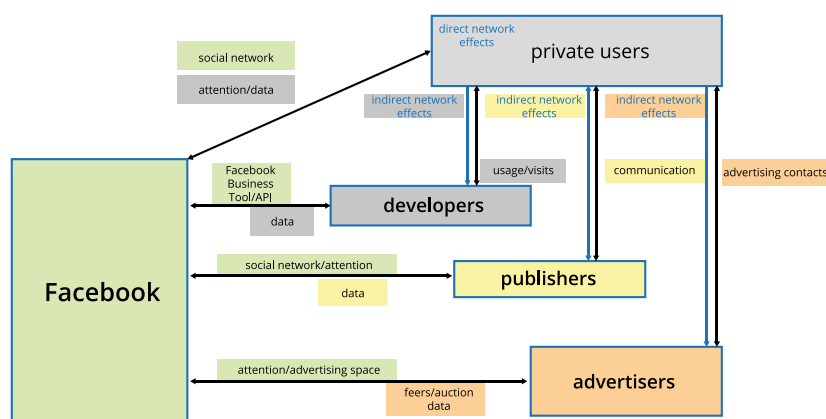

573 <https://googleblog.blogspot.com/2012/01/updating-our-privacy-policies-and-terms.html>.

574 <https://www.facebook.com/about/privacy/update>.

Facebook receives information from third-party websites and services, namely which websites and apps a Facebook user uses and registers with. As a result, Facebook is able to assign a broad set of data to the individual user accounts.⁵⁷⁵

3.6.3. Conclusions: Linking of P2C and P2B governance as characteristic of multi-sided markets

Distinguishing between P2B and P2C governance for analytical reasons may not conceal the fact that the conflation between both layers is central for the business model of many digital platforms. The business model of Facebook, for instance, hinges upon the connection of key user groups such as private users, advertisers, publishers, and developers through Facebook in order to realize indirect network effects.

Source: Bundeskartellamt (B6-22/16)⁵⁷⁶

While nuances of course exist, none of the examined platforms displays significantly different characteristics in its governance structure. More generally, it seems that competition between platforms and their respective competitors does **not produce high variation with regard to T&Cs**. Newly entering platforms seldomly highlight deviations from standard P2B T&Cs to sharpen their business profile (unlike with regard to P2C privacy rules, where high privacy is used as a signifier).

In terms of the geographical **localization of the value capture**, the more the service towards end users is digital (eg Amazon Web Services), the more globally a platform will offer its services. Inversely, a close connection to culturally loaded services or regulated service sectors (eg transportation) entails local competitors. This holds true specifically for China, where Google, Amazon, Airbnb and Tinder face local competition. Also, the availability of global platform services in contested territories, such as the West Bank, regularly creates controversy.⁵⁷⁷

⁵⁷⁵ For a detailed factual description cf Bundeskartellamt, Decision of 6 February 2019, B6-22/16, paras 68-150.

⁵⁷⁶ Bundeskartellamt Decision of 6 February 2019, B6-22/16, https://www.bundeskartellamt.de/SharedDocs/Entscheidung/EN/Fallberichte/Missbrauchsaufsicht/2019/B6-22-16.pdf?__blob=publicationFile&v=4.

⁵⁷⁷ For the – now reversed – decision of Airbnb to remove listings from Jewish settler homes in the Westbank cf <https://www.theguardian.com/technology/2019/apr/10/airbnb-reverses-decision-to-remove-israeli-west-bank-homes-from->

Across all case-studies, both smaller and more **strategic mergers** have been an important driver of growth and technological advancement.⁵⁷⁸ As illustrated in the case of *Airbnb*, merger activities in an early phase of a pioneering corporate development sought to clear market from competitors with a similar business model to ensure competitive advantage while at a later stage, mergers ensure technological progress and expansion to other business sectors in view of building an ecosystem.

Finally, some variations with regard to the **transition from platforms to ecosystems** can be observed. While some of the case studies reveal paradigm cases of ecosystems (such as Google, Amazon, Airbnb), the dating app Tinder has been on a rather singular track and has not created its own ecosystem. The dating platform is part of a holding (*Match Group*) and must comply with a corporate strategy that may potentially harm its interests. Also, as *Tinder* offers its service directly to its consumers, it relies on a P2C type of relations that leaves little room for relations with other businesses and third parties. In its P2C relations, contractual governance of the above mentioned type (limitation of liability and broad discretion to use user data) can be found.

Chapter 4: General Conceptual Framework

Ioannis Lianos^{579*}

4.1. A complex economy perspective for digital competition law

4.1.1. Competition law in liminal times: beyond neoclassical price theory

As the global economy is incurring a process of transformation by the ongoing ‘fourth industrial revolution’, competition law is traversing a ‘liminal’ moment, a period of transition during which the normal limits to thought, self-understanding and behaviour are relaxed, opening the way to novelty and imagination, construction and destruction.⁵⁸⁰ The development of digital capitalism the last three decades has led to an important ‘information overload’⁵⁸¹, induced by this rapid revolutionary change. Competition authorities in Europe and elsewhere have been rather slow to react, as they have tried unsuccessfully to deal with the problem by applying industrial capitalism era competition law to the ‘next generation competition’ of the post-industrial informational capitalism.

Most competition authorities and competition law scholars have addressed this process of transformation by focusing on its technological dimension and its impact on business models. Their work usefully explores the ways the existing competition law framework may apply to these new business models, or to these new technologies, in order to address the technological challenges of the moment. Others have attempted to theorize the impact technology may have on the concept of competition in order to show that the current framework might be myopic⁵⁸². This effort has identified the problem but has not delved that deeply into suggesting a new theoretical framework for competition economics and competition law, and has stopped short in offering new operational concepts that could be integrated in positive law.

All these initiatives to a certain extent strive to address the question of the scope, role and function of competition law in the post-industrial capitalism era. However, they have not so far integrated this question in the broader debate over the new processes

579 * Andrew McLean contributed to Section 4.3.1.2., and also read through the whole text providing useful comments and suggestions. The author would like to thank Igor Kharitonov for excellent research and editorial assistance as well as for contributing to the drafting of some parts of this research as indicated in a footnote further below.

of value generation and capture in the era of digital capitalism and the complex economy to which it has given rise to. This complex digital economy is formed by a spider web of economic links, but also their underpinning societal relations, between different agents. As we will explore in the following Section, in order to understand this emergent non-deterministic behavior of such complex system, one needs to refer to concepts such as increasing returns, leverage points, tipping points and path dependence⁵⁸³.

However, competition law still lives in the simple world of neo-classical price theory (NPT) economics, which may not provide adequate tools in order to fully comprehend the various dimensions of the competition game and to guide public policy and competition law enforcement in the digital age and the complex interactions between economic actors that these new technologies enable. The emphasis put recently by competition authorities on multi-sided markets in order to analyse restrictions of competition in the data economy illustrates the agents' changing roles and the complexity of their interactions, as the same agents can be at the same time consumers and producers while their personal data raw material for the value generation process.

It becomes therefore essential to uncover the new value capture and value generation processes in operation in the digital economy, and draw lessons for the optimal design and enforcement of competition law, rather than take the established competition law framework as a given and try to stretch within it a quite complex reality that may not fit this Procrustean iron bed. The stalemate of fitting multi-sided markets theory in the context of a kind of loose operation of market definition as a transaction platform or of determining the existence of a restriction of competition by effect but facing the difficult consideration of out-of-market efficiencies, provide an illustration of the inherent difficulties, and ultimately of the futility, of such exercise. We consider that competition law should first focus on the way the value brought by innovation in the digital economy is captured, shared and generated, the three processes being intrinsically linked, before exploring how this process affects the competitive strategies of firms and the broader selection environment in the economy. Once this effort is completed, it would be possible to re-target and re-conceptualise the competition law tool. We identify three important manifestations of this increasing complexity that may have significant implications for competition law in the years to come.

The first relates to futurity, a term originally coined by John R. Commons to describe the reorientation of economies towards the future. This is linked to the fledgling practice of treating businesses as 'going concerns', measuring their value in terms of their anticipated future profits.⁵⁸⁴ In today's financialised digital economy the most important driver of value creation is pots of gold being found far into the future and eventually linked to future expected monopolistic rents of the digital economy players.

The futurity trend is particular salient in the funding of blockchain technology projects with Initial Coin Offerings (ICOs) emerging as the main source of funding for blockchain startups, even before any promise in their 'white paper' has materialized in real product

583 See our analysis in Section 3.1.2.

584 John R Commons, *Institutional Economics: Its Place in Political Economy* (The University of Wisconsin Press 1934).

markets. Digital platforms are also ‘madly’ valued by financial markets, in a way that does not seem to correspond to their current cash flow, but which increasingly relates to high expectations for phenomenal profits in the not-so-immediate future, because of their position as gatekeepers controlling important bottlenecks in the digital economy (e.g. operating systems, search engines, app stores, the cloud)⁵⁸⁵. The relatively recent focus of competition law on innovation, rather than allocative efficiency, also provides an additional example of the impact of futurity, this time in competition law doctrine. Futurity and its linkage to financialization challenges the traditional approach of competition law, which focuses on market power perceived as the ability to raise prices and reduce output in a well-delineated and existing product market.

Second, the harvesting and processing of personal data enables the personalisation of both production and distribution. It is increasingly acknowledged that data collection is key in the ability of firms to compete in the future Internet of Things (IoT), or Internet of Services (IoS). Firms harvest personal data by attracting users and monetise this data in advertising ‘attention markets’. Although consumers often do not pay for the zero-priced products provided by the platforms, other than providing their data, their autonomy to self-determine the level of privacy they enjoy is curtailed by the ‘take it or leave it’ nature of their exchanges with digital platforms, on which they are dependent in order to operate (work, develop social interactions, be entertained) in their daily life. Consumers cannot easily and costlessly escape from this technological dependence by switching to alternative options, in view of the high switching costs, to the extent that they may not be able to port all their data and digital relations to the competing platforms, and the lack of competition resulting from the ‘winner takes most’ nature of most of these markets.

Data analytics connected to the use of software for predictive modelling, will also reinforce the competitive advantages for the digital platforms holding most of the data, or the attention of users, this being ultimately crystallised in ‘architectural advantage’. This entrenches their monopoly and/or monopsony position in the value chain⁵⁸⁶. Much of this data will relate to the digital identity of the consumer and will enable companies to draw fairly accurate preference maps for each of their clients. In this era of ‘mass personalisation’⁵⁸⁷ the focus will not only be on ‘attention markets’⁵⁸⁸, but on the development of bespoke products to the individual preferences of the consumers. Once a specific amount of data is harvested, these personalised markets may tip to monopoly, if only one platform or ecosystem has the capabilities to harvest and analyse the data as well as to perfectly satisfy the individual consumer’s demand function in an array of

587 Deloitte, ‘Made to Order: The Rise of mass personalisation’ (2015), available at <https://www2.deloitte.com/content/dam/Deloitte/uk/Documents/consumer-business/deloitte-uk-consumer-review-mass-personalisation.pdf>.

588 On this concept, see T. Wu, Blind Spot: The Attention Economy and the Law (March 26, 2017). Antitrust Law Journal, Forthcoming. Available at SSRN: <https://ssrn.com/abstract=2941094>; D. S Evans, The Economics of Attention Markets (October 31, 2017). Available at SSRN: <https://ssrn.com/abstract=3044858>.

products. Firms may be able to monetize this power in financial markets and to leverage it or convert it in other spheres of social activity (e.g. political power, cultural power). Firms may also use this privileged access to the ‘mind’ and attention of users in order to reinforce their positional advantage in the specific value chain vis-à-vis firms forming part of their value ecosystem or which are dependent on them for reaching these users.

The third important change is the move from markets to cybernetics. In the static model of competition applied by competition authorities, prices provide complex information in a condensed way to producers about consumer preferences, thus enabling conventional markets to work. The new data harvesting and processing techniques are nonetheless important game-changers. First, the use of data improves market matches. As customers keep shopping, digital assistants learn how to make even better recommendations, most of this ‘learning’ taking place completely or largely unassisted by humans, as data is fed into machines that continuously update their algorithms. Algorithmic firms gather comprehensive personal data on their customers, and by doing so they undo the need to rely on decentralized markets to acquire knowledge on the preferences of consumers. Preferences are not materializing through choice but algorithmically predicted. Second, they may also more easily discriminate between groups of consumers/users, by choosing a price structure that would subsidize some and ‘tax’ with higher prices others or by offering a personalized price. Price loses its central position as an indicator of consumer preferences expressed in decentralized markets. Consumers are not in the driving seat, as buyers are influenced both by explicit recommendations and by the ways in which options are filtered and presented, in particular as their ‘trust in the machine’ may be higher than trust in humans. Digital platforms may thus replace markets to a certain extent, in particular in a “winner takes most” world, where in the presence of strong network effects digital markets may easily ‘tip’. Platforms are not just ‘matching’ different groups of users but become prediction machines with the ability to manipulate or influence users’ choice. The way these digital platforms finish by regulating their ecosystems, but also manage consumer demand, presents some similarities to a private version of a centrally-planned mini-economy and the field of cybernetics.

4.1.2. What are the distinctive characteristics of a complex economy perspective?

As discussed in the previous Section, ‘simple economics’ rely on partial equilibrium thinking grounded on few propositions (e.g. rational choice), reducing heterogeneity by grouping the various elements that compose the system in few broad categories (e.g. the consumer, the firm, or in other words the ‘representative agent’). It also ignores the ‘connective complexity of the economy’ (the net of links that shape the economy, but also their underpinning societal relations, being kept very simple due to the hypotheses of complete information so that each element of the economy can contact and evaluate all others at no cost, the network of connections being irrelevant to the functioning of

the system)⁵⁸⁹. Unfortunately, using the same tools to understand complex economies and societies fails, because it ignores the variety of adaptive processes at play.

Some definitions of complexity focus on the internal structure of the system, rather than the complexity of the behaviour, qualifying a system as complex ‘when it is composed of many parts that interconnect in intricate ways’⁵⁹⁰. That said, an important concept in complexity theory is ‘emergence’. Contrary to neoclassical economics where the behaviour of the system is assumed to reflect the behaviour of its constituent parts, complex economics accepts that there is a disconnection between an individual’s localised behaviour and how this aggregates into global behaviour⁵⁹¹. As a result of this disconnect, the overall emergent behavior of a complex system is difficult to predict, even when subsystem behavior is readily predictable. Small changes in inputs or parameters may thus produce large non-linear changes in behaviour. Markets may tip once a critical threshold is reached, they are characterized by network effects and various feedback loops, positive or negative. This should not be considered as a criticism to competition law enforcement, in view of the difficulty sometimes to determine with appropriate precision the effects of a specific conduct on the competitive process or the interests protected by competition law.

Complex systems are also dynamic as they learn, evolve, and adapt, generating emergent non-deterministic behaviour, which breaks with the assumptions of equilibrium behaviour of simple economics⁵⁹². They are not populated by homogeneous predictable agents, but by a collection of heterogeneous agents (individuals, organisations etc.), whose state influences and is influenced by the state of others (for instance situations of social contagion), and whose interactions give rise to global properties of the system that are more than the sum of individual behaviour. As the interactions within complex systems are not independent, various feedback loops can enter the system and affect individual decisions. This complex digital economy is characterised by

- increasing returns to scale and scope,
- feedback loops, when interactions between agents are not independent, which may alter fundamentally the dynamics of the system. In systems with negative feedback, changes get quickly absorbed and the system gains soon stability, whereas in a system with positive feedback, ‘changes get amplified leading to instability’⁵⁹³.
- leverage points, that are ‘places where the system can be altered or changed’,
- tipping points, ‘where a system suddenly changes state based on a small change in a parameter of the system’, and

593 *Ibid.*, 50.

- path dependence, which means that ‘the current possibilities of the system are in some sense constrained by the past choices that were made’⁵⁹⁴.

The study of complexity also demands different strategies of engagement and new methodologies. As David Colander writes, ‘(i)instead of trying to find a formal analytical model, with a formal solution for these complex phenomena, complexity theory looks for patterns that develop when non-linear processes are repeated for long periods of time’, the mathematics used being ‘non-linear dynamics’, and the models generally used being ‘open models with no unique deterministic solution. Many solutions are possible; which one is arrived at depends upon initial conditions and the path the model follows’⁵⁹⁵. This puts emphasis on computation and brings to the center of the economic enquiry simulation approaches that rely less on theory and more ‘on conjectures and patterns that temporarily fit’⁵⁹⁶. In simple economics, models are constructed for prediction and derive from a set of first principles, which often include assumptions as to the abilities and motives of the underlying agents, these being linked through mathematical reasoning and deduction with axioms, the latter being associated with the notion that ‘social systems tend toward equilibrium states’⁵⁹⁷. In contrast, the computational models are used as mapping tools⁵⁹⁸. They provide the terrain for computational experiments and thus aim to generate only inductive proof. In these models, ‘(a)bstractions maintain a close association with the real-world agents of interest’ and ‘uncovering the implications of these abstractions requires a sequential set of computations involving these abstractions’⁵⁹⁹. These computational models should enable the consideration of the complicated preference structures of the population, and its heterogeneity, so as to account for their more elaborate set of choices.

One of the tools that is often used to generate these computational models is ‘agent-based modelling’, which attempts to depart from the abstraction of the underlying agents in a system into a single representative agent, all agents being subsumed into a single simplified agent⁶⁰⁰. Although agent-based modelling cannot completely dispense of this step, as even if it does not rely on a representative agent, there is some level of abstraction from the real-agents by constructing an artificial adaptive agent, it allows for the direct interaction between these agents (hence the focus on ‘adaptive’). Adaptation can be incorporated through different means, such as employing population-based search evolutionary algorithms (e.g. a genetic algorithm) that draw on a metaheuristic inspired by the process of natural selection and rely on a pool of potential solutions, rather than one⁶⁰¹.

594 See the discussion in W. Rand, *Complex Systems: Concepts, Literature, Possibilities and Limitations*, in B.A. Furtado, P.A.M. Sakowski, M.H. Tóvolli (eds.), *Modeling Complex Systems for Public Policies* (IPEA, 2015), 37, 41.

598 *Ibid.*, 36.

599 *Ibid.*, 65.

600 *Ibid.*

601 The process involves several steps, beginning with a set of individuals (population), each individual being characterised by a set of parameters (variables or ‘genes’), these being joined into a string to form a solution (‘chromosome’). A fit-

These interactions depend on, and determine the boundaries of, the 'space' within which the agents are contained, the space being often endogenous in a system. The point is that determining the relevant 'space' or 'field' of interaction cannot be done before fully engaging computationally with the interactions of the agents themselves, also taking into account the possibility of asynchronous activation, each agent awaking at a different time, processing what information is currently available and thus by its action altering 'the information ether' that the other agents will face when activated⁶⁰². Such an approach may cater for situations in which, assuming that the focus is on competitive interactions, there is a potential competitor.

In view of its focus on interactions between agents, complex economics models social systems as networks of nodes and ties. These ties act as pipes through which things (e.g. information) flow. This brings to the fore the role of networks as spaces of interaction. This has important implications on the understanding of power relations within systems. For instance, in 'small worlds' networks, where each agent is first connected to a set of neighbouring agents, information can be transmitted between any two nodes using, typically, only a small number of connections (allowing the generation of 'six degrees of separation'), which shows the crucial role in the operation of the system of only a few intermediate nodes⁶⁰³. If however a network is solely composed of neighbourhood connections, 'information must traverse a large number of connections to get from place to place', thus limiting the power/influence of the intermediary nodes⁶⁰⁴. Hence, the position of an agent in a network may be a source of advantage and power.

The type of connections linking the agents is also a crucial issue. The 'strength of weak ties' is a well-known contribution in the field of sociology⁶⁰⁵, showing that weak ties are surprisingly valuable because they are more likely to be the source of novel information than strong ties. This comes out of the hypothesis that if A and B have a strong tie, they are likely to have many acquaintances (weak ties) in common. Strong ties create transitivity which creates a closed world with redundant ties. Bridges are ties connecting different parts of the network: removing the tie between Y and Z would mean the shortest path from Y to Z would be quite long. These are more likely than other ties to be sources of novel, non-redundant information. Weak ties are more likely to be bridges than strong ties. According to another theory, structural holes, which denote a lack of connection between two nodes that is bridged by a broker, provide information benefits and may lead to rewards, thus emphasising the power the broker may draw

ness function measures the ability of an individual to compete with other individuals (how 'fit' an individual is), each individual being given a fitness score. The selection of the fittest individuals to pass their 'genes' to the next generation depends on their fitness score. The next stage is crossover where for each pair of parents to be mated, a crossover point is chosen at random from within the genes. Certain new offsprings formed from the crossover are subjected to a mutation with a low random probability in order to maintain diversity in the population, the algorithm being terminate if the population has converged (does not produce offspring which are significantly different from the previous generation).

603 *Ibid.*, 155.

604 *Ibid.*

605 M.S. Granovetter, *The Strength of Weak Ties*, (1973) 78(6) *American Journal of Sociology* 1360.

from his positioning within the system⁶⁰⁶. This theory does not focus, as the ‘strength of weak ties’ theory on the strength of the relationship between two entities, but rather on the lack of a tie between entities (the ‘chasm’) that may become source of power for the broker. Complex economics allow for these different sources of wisdom (e.g. economic sociology, network theory, neuro-economics) to be integrated in the way the computational models are constructed, thus augmenting their explanatory power in the context of a complex set of interactions between heterogeneous agents.

Computational models may also allow for a greater heterogeneity of the agents whose interactions will be modelled, for instance by developing ‘an ecology of agent types, each relying on different behavioural governing mechanisms’⁶⁰⁷, although as mentioned above it cannot completely dispense with the constitution of representative agents. This enables the theorist to construct computation models ‘bottom-up’, any abstraction focusing ‘over the lower-level individual entities that make up the system’⁶⁰⁸. The model also integrates learning and adaptation as a byproduct of this direct interaction, thus incorporating frameworks for emergence, the model being flexible enough so that ‘new unanticipated features’ may naturally arise within the model⁶⁰⁹. This contrasts with the ‘top-down’ modelling of simple economics which ‘abstracts broadly over the entire behaviour of the system’⁶¹⁰. The point is that even if we managed to acquire ‘a complete specification of the psychological aspects of behaviour or the probability of interaction’ of all the underlying agents, it would still be difficult to fully understand the macrolevel implications of their interactions, in particular because the models of simple economics do not anticipate emergence⁶¹¹. Emergence does not deny the possibility for an equilibrium state, however it indicates that this equilibrium state may not be unique and may ‘depend on various random elements of the model or nonlinearities’, the system being in ‘perpetual motion’⁶¹².

This computational modelling may aim to unveil a simple structure of interactions, abstracted from the behaviour of artificial adaptive agents, or a more complicated structure of interactions, in case the computational modelling and the use of simulations allows for the constitution of ‘artificial life’ or artificial worlds. These would rely on a model of ‘adapting, communicating, multiple-game playing artificial agents’⁶¹³. One may think of reproducing the digital twin of a network or ecosystem, linking the real and digital worlds, using AI to turn data into actionable insights. First, various sorts of data may be harvested, and then millions of examples of curated data could be leveraged to train deep learning neural networks. At the next step, neural networks may be used to approximate parts of the computational model. This holds the potential for evaluating the

effectiveness of tailored treatments and experiment with various forms of intervention, using advanced simulation in order develop more precise prognoses. These tools may enable a better and quicker filtering of the situations in which more elaborate competition law analysis is needed, and may provide solid evidence for building counterfactuals in competition law investigations.

Some of the theoretical insights and concepts of complex economics have been gradually incorporated in competition economics' scholarship and some in competition law enforcement. Terms, such as increasing returns, tipping point, leveraging point are widely used by scholars, competition authorities and courts and form now part of the current mainstream approach in competition law and economics. However, the tools and methodologies of complex economics have not yet made any impact on competition law enforcement, but also on competition law and economics literature. We consider that it is time competition authorities make the effort to engage with these new tools, and to develop capabilities for engaging with computational economics. In view of the large availability of data, and the complexity of the issues raised by digital platforms and networks, the digital economy offers plenty of opportunities to try these new methodologies and tools, such as agent-based modelling, computational models, digital twins etc. In our view one of the major impediments for the use of such novel approaches is the rigidity of the 'consumer welfare' standard that has enthused so far the Geist of competition authorities and has provided the theoretical framework of their action the last few decades. We consider that the emphasis put on 'consumer welfare' is very much linked to the simple economics of the 'representative agent', and does not account for the heterogeneity of agents and the complexity of their preference structures, in particular as competition law becomes more 'polycentric'⁶¹⁴.

This discussion leads us to explore how the current consumer welfare standard applied by competition authorities may fare in the era of digital competition and a complex economy.

4.2. Is the consumer welfare standard adequate to deal with the competition challenges of digital competition, and how could this consumer welfare standard be defined?

4.2.1. The pitfalls of the consumer welfare standard in a complex digital economy

The concept of consumer welfare is one of the most commonly referred goals of competition law, by competition authorities and also competition law and economics scholarship globally. The concept is in reality quite fuzzy and may include multiple dimensions of 'consumer harm' that may trigger competition law enforcement:

614 I. Lianos, Polycentric Competition Law, (2018) Current Legal Problems 161.

- (i) In the economic jargon, the protection of consumer surplus constitutes an important part of the total welfare standard test. In this context, consumer surplus denotes the consumer part of the deadweight loss suffered as a result of the restriction of competition. For example, a price increase might lead to a volume effect that would be suffered by a certain category of consumers: because of the price increase some consumers will not be able to buy the product any more, although past consumption patterns (revealed preferences) indicate that they would have preferred to do so, if the price had not increased. In this sense, the case against the exploitation of substantial market power is not linked to the transfer of wealth from consumer to producers over those (infra-marginal) units of output still sold, but merely on the lost transactions which could have taken place under a more competitive scenario.⁶¹⁵ In any case, for operational purposes the focus is on consumer harm, as captured by the (likelihood of) higher prices and lower quantity; bearing in mind that in practice hardly anyone in the field of enforcement ever actually attempts to measure/estimate actual changes in either total or consumer welfare.⁶¹⁶ Under this narrow definition of consumer surplus, the overcharge paid by the consumers as a result of the price increase should not be of concern for competition law enforcement, as it constitutes a wealth transfer from the buyers to the sellers. The suppliers may be in a position to compensate (hypothetically, not actually) the loss that consumers have suffered while still being able to compensate with this wealth transfer their own losses following the volume effect (producer surplus). In this configuration the situation will be Kaldor-Hicks efficient. We will call this view of consumer harm: the 'consumer surplus standard'.
- (ii) There is also an argument to move beyond consumer surplus and include in the analysis the wealth transfer that consumers have incurred because of the overcharges following the restriction of competition. These may relate not only to higher prices but could cover any other parameter of competition, such as quality, variety, innovation. In this case, both the loss of consumer surplus and wealth transfers will be compared to the total efficiency gains pertaining to the supplier(s), thus enabling a cost benefit analysis of the effect of the conduct on the welfare of a specific group of market actors, direct and indirect consumers (not all market actors). The idea is that following the change from an equilibrium situation to another, the consumers of the specific product will benefit from a surplus and/or wealth transfer, in the sense that their ability to satisfy their preferences will in

615 The irrelevance of distributional concerns is normally justified with reference to the 'compensation principle' (also labelled Kaldor-Hicks efficiency criterion, or Potential Pareto Improvement) which posits that, if gainers can compensate losers and still be better-off, the change observed in the partial equilibrium analysis is desirable. That is to say, even if the compensation never actually takes place, it is down to the political system to take care of the redistribution of the 'pie' (the separability thesis).

616 There are some examples of competition authorities commissioning studies into the effects of their past decision, thus basically assessing whether their intervention (or lack thereof) has increased consumer surplus. For an overview, see, OECD (2011), *Impact Evaluation of Merger Decisions*, available at <http://www.oecd.org/daf/competition/Impactevaluationofmergerdecisions2011.pdf>.

crease. Again, for clarity this standard will be referred to as the 'consumer welfare standard'.

Usually, looking at changes in total or consumer surplus makes no difference in practice, since both tend to move in the same direction, as graphically captured by the deadweight loss, which is the loss of consumer and producer surplus due to a restriction in output caused by an increase in price, and stands to signify how allocative efficiency has worsened due to the exploitation of market power. As put by Werden '[a]nything enlarging the metaphorical pie offers a potential Pareto improvement because it is possible to make at least one individual better off while no one is worse off⁶¹⁷'. However, there may be situations in which a specific conduct, while leading in theory to a potential increase of the pie, worsens the situation of consumers, who not only capture less than before, but may also see their situation worsen. In these cases, a consumer welfare standard will focus on the wealth transfer from consumers to other market players. Let's imagine that thanks to the exclusion of a less (productively) efficient rival (i.e., as a result of a merger or foreclosure) a larger share of demand is now allocated to a dominant firm with lower costs, so that the supply curve shifts outward to the right. At the same time, though, the exclusion of a less efficient rival will reduce competitive constraints in the market making it possible for the dominant firm to increase prices. The reduction in costs may not be large enough to offset the increase in price.

- (iii) Some authors argue also that competition authorities should aim to preserve an optimal level of 'consumer choice', defined as 'the state of affairs where the consumer has the power to define his or her own wants and the ability to satisfy these wants at competitive prices'⁶¹⁸. This concept seems broader than the concepts of 'consumer surplus' and 'consumer welfare' (the latter including consumer surplus plus the wealth transfer because of the overcharge) as it may include other parameters than price, in particular 'variety'. The same authors have used interchangeably the term of 'consumer sovereignty', which is defined as 'the set of societal arrangements that causes that economy to act primarily in response to the aggregate signals of consumer demand, rather than in response to government directives or the preferences of individual businesses'.⁶¹⁹ Defining the 'optimal degree' of consumer choice or consumer sovereignty and measuring it using some operational parameters seems however a daunting task. Consumer sovereignty may be conceptually appealing but may prove empirically weak to implement in competition law enforcement.

617 G.J., Werden 'Antitrust's Rule of Reason: Only Competition Matters', (Mimeo Washington, DC: U.S. Department of Justice – Antitrust Division, 2003), 28.

618 R.H. Lande, 'Consumer Choice as the Ultimate Goal of Antitrust' (2001) 62(3) University of Pittsburgh Law Review 503, 503. For an import of this concept in EU competition law, see P. Nihoul, N. Charbit & E. Ramundo (eds.), Choice – A New Standard for Competition Law Analysis? (Concurrences, 2016).

619 N.W. Averitt & R.H. Lande, 'Consumer Sovereignty: A Unified Theory of Antitrust and Consumer Protection Law' (1997) 65 Antitrust Law Journal 713, 715 .

- (iv) Consumers, or more generally the public, may also benefit by a vivid competitive process. The idea is that the preservation of a competitive process is essential to prevent a prolonged departure from the optimal outcome usually associated to competition. Another approach may be deontological and would argue that the competitive process and the economic freedom of undertakings to participate to this competitive process must be preserved, irrespective of the effects of such competition on social or consumer welfare. The German ordoliberal school has arguably put emphasis on the competitive process indicating that we should be concerned if ‘the number of freely competing producers is artificially reduced in ways that do not result from the normal process of competition itself’, and ‘where this reduces the scope of alternatives among which consumers may freely chose’.⁶²⁰ Defining the competitive process as ‘the process of sellers and buyers forming improving coalitions’, other authors argue that ‘[competition law] protects the *potential beneficial trades between* competitors and consumers’, recognising ‘both consumers and thwarted competitors’ ‘antitrust rights, even though antitrust protects ‘competition and not competitors’.⁶²¹ Such an approach may dispense, to a certain extent, with focusing on all practices that reduce consumer welfare in equilibrium and may provide a useful starting point for the competition assessment, or for some a substantial part of the competition assessment.
- (v) As innovation is considered a major engine of growth, public authorities play a direct role in fostering innovation⁶²², but also in supporting the emergence of an innovation-friendly market environment. The role of the competitive process in the promotion of innovation is well recognized and widely accepted. Certainly, research and development requires up front investments for uncertain rewards. For instance, intellectual property rights were initially conceived as an exception to the rule of competitive markets. By providing some economic rents, intellectual property rights are supposed to ensure that the inventor has adequate incentives to innovate at the first place. Although IP may provide some certainty over the ability of an undertaking to retain the benefits from the innovation it put in place (and internalise the positive externalities thus produced), the social return to innova

Behrens, ‘The Ordoliberal Concept of ‘Abuse’ of a Dominant Position and its Impact on Article 102 TFEU (September 9, 2015) Nihoul/Takahashi, Abuse Regulation in Competition Law, Proceedings of the 10th ASCOLA Conference Tokyo 2015, available at SSRN: <https://ssrn.com/abstract=2658045> . For a translation in English of the views of one of the principal authors of the ordoliberal group, see W Eucken, The Foundations of Economics – History and Theory in the Analysis of Economic Reality (1992, first published in 1939, Springer).

621 See A. Edlin & J. Farrell, Freedom to Trade and the Competitive Process, in R Blair & DD Sokol (eds.), The Oxford Handbook of International Antitrust Economics, Vol. I (OUP, 2014), Chap. 13.

622 This is either done through public investment in science and basic research, which can play an important role in developing general-purpose technologies and, hence, in enabling further innovation, as well as public support to innovative activity in the private sector, which is usually taking the form of a mix of direct and indirect instruments such as tax credits, soft loans, direct support etc. On the important role of the State in supporting innovation, see M. Mazucatto, The Entrepreneurial State: debunking public vs. private sector myths (Anthem 2013).

tion largely exceeds its private return.⁶²³ In reality, imperfect IP protection may lead the competitors to gain some of the rewards from the rival's innovation (the problem of limited appropriability).⁶²⁴ Technological spillovers and imitation across the industry or cross-industries may boost growth to a considerable extent, without being possible that these indirect benefits are appropriated by the IP holder, thus illustrating the inadequacy of a policy relying on intellectual property rights only to spur innovation and the importance of public funding of research. It has been argued that disruptive innovation may also challenge monopoly positions that become temporary (the process of 'creative destruction').⁶²⁵ Determining what is the appropriate market structure for innovation remains however an open and hotly debated issue.⁶²⁶ The rise of digital platforms may have both positive and negative effects on innovation. In theory, digital platforms have been investing considerably in R&D, although their R&D intensity is lower than that observed in the pharmaceutical industry, even if the amount of R&D expense, because of their capitalisation may seem quite high. Figure 4.1. below, illustrates comparative R&D expenditure as a percentage of net income between the five largest tech and pharmaceutical companies by market capitalisation.

Figure 4.1.: Big Tech vs. Big Pharma – R&D expenditure as a percentage of net income, 2016-18

623 This was highlighted by K. Arrow, *Economic Welfare and the Allocation of Resources for Invention in The Rate and Direction of Inventive Activity: Economic and Social Factors* (NBER, 1962) 609.

624 Ibid., 619.

625 J. Schumpeter, *Capitalism, Socialism and Democracy* (1942, published by Harper & Bros. in 1950) 83, noting that 'The opening up of new markets, foreign or domestic, and the organizational development from the craft shop and factory to such concerns as U. S. Steel illustrate the same process of industrial mutation – if I may use that biological term – that incessantly revolutionizes the economic structure from within, incessantly destroying the old one, incessantly creating a new one. This process of Creative Destruction is the essential fact about capitalism. It is what capitalism consists in and what every capitalist concern has got to live in'.

626 For a critical analysis, see the companion volume. See also, J Baker, 'Beyond Schumpeter vs. Arrow: How Antitrust Fosters Innovation' [2007] 74 *Antitrust Law Journal* 575; RJ Gilbert, 'Competition and Innovation' in WD Collins (ed) [2008] 1 *ABA Section of Antitrust Law, Issues in Competition Law and Policy* 573.

However, we also observe that the Big Tech platforms have engaged in intensive M&A activity, buying not only a number of potential competitors (contributing to the problem of ‘killer acquisitions’), but also vertical and conglomerate mergers, quite often in order to control technologies that could complement well their core activities. Figure 4.2. illustrates the scale of acquisition activity by Amazon and Alphabet over the last decade, and highlights the largest of these transactions by deal value.⁶²⁷ Amazon and Alphabet were involved in 102 and 195 transactions, respectively, over the period.⁶²⁸

Figure 4.2.: No. of M&A deals completed by Amazon and Alphabet, 2009-19

Source: Author's compilation

Although Big Tech retain earnings and do not distribute, at least as much, to their shareholders, they do not seem to significantly reinvest these retained earnings in R&D as most of them sit on large amounts of unutilised cash.⁶²⁹ This is not a unique story for Big Tech. Investments in R&D are increasingly concentrated in a few sectors across most

⁶²⁷ ‘Investments’ should be taken to mean partial investments in a company. Large coloured circles indicate the deal value exceeded \$1 billion, small coloured circles indicate the deal value to be less than \$250 million, and clear circles denote that the deal value is unknown. The original graph produced by The Economist also contains the acquisition and investment activity of Microsoft, Facebook and Apple. Microsoft, Facebook and Apple were involved in 117, 68 and 71 transactions, respectively. The Economist, Calls to rein in the tech titans are getting louder (16 July 2016) <<https://www.economist.com/graphic-detail/2019/07/16/calls-to-rein-in-the-tech-titans-are-getting-louder>> accessed 14 August 2019.

⁶²⁸ *ibid.*

⁶²⁹ See R. Waters, ‘Google parent Alphabet overtakes Apple to become new king of cash’ (31 July 2019) <<https://www.ft.com/content/332dd974-b349-11e9-8cb2-799a3a8cf37b>> accessed 14 August 2019.

of the mature economies⁶³⁰. Firms may also employ cash hoarding as a defensive tool in order to protect their current stock of technology, and not in order to invest in new technologies. Statistics show that business investment has steadily declined since the late 1970s, if measured as a share of GDP⁶³¹. The concept of research has also changed. A lot of money is actually spent on product adaptation, design and development, copying a feature or add on from another product or adjusting the product stock to local demands – i.e. the development – and little is spent on the research⁶³². Growth in real investment on R&D is declining, the US National Science Foundation reporting that its measure of R&D intensity has flat-lined since 1995⁶³³. Many companies have reacted to problems with their R&D strategy by outsourcing R&D to smaller firms that can take bigger risks⁶³⁴. Similar processes are in operation in the digital sector where a significant amount of R&D depends on start-ups, many of which will not develop to unicorns. Once the R&D investments have begun to mature into innovative products, large companies have acquired them and integrated them into their global value chains⁶³⁵. This may affect the innovation and entrepreneurial ethos and consequently lead to the loss of opportunities to innovate in comparison to a more competitive industry structure. In the absence of some assurance that large firms will invest their profits to promote innovation and increase the production possibility frontier, it would be imprudent to provide a *carte blanche*.

Box 4.1. Goals and objectives of BRICS competition laws and the digital economy

On the adequacy of the relevant national competition laws to face the challenges arising from the digital economy, especially whether the goals and the objectives are sufficient to address challenges arising from the digital economy, most BRICS economies find the matter requiring further analysis or redesign of existing tools:

BR The competition law establishes the prevention and the restraint of violations against the economic order as the main goal of the Brazilian Competition Defense System. This goal addresses conducts involving the digital economy as well. So no revision of goals is required. Further the current competition law is very flexible to address the specific issues related to digital markets. It has been applied successfully in several competition cases involving these markets in the recent years.

630 See for example G. Clark, 'Winter Is Coming: Robert Gordon and the Future of Economic Growth', (2016) 106(5) American Economic Review: Papers & Proceedings 68-71.

631 Ibid, p. 29.

632 F. Erixon and B. Weigel, *The Innovation Illusion* (Yale University Press, 2016), 33.

633 R&D intensity, measured as the share of industry-level R&D expenditure to sales, increased in the seed sector from 11.0% in 1994 to 15.0% in 2000 before falling back to 10.5% in 2009.

634 See for instance, P. Gleadle et al., 'Restructuring and innovation in pharmaceuticals and biotech: The impact of financialisation', (2014) 25 Critical Perspectives on Accounting 67-77

635 Comanor and Scherer point out to how M&A may have been used as a safety net for companies against the uncertain prospects of innovation projects or to acquire synergies in R&D, W. S. Comanor and F. M. Scherer, 'Mergers and innovation in the pharmaceutical industry', (2013) 32 Journal of Health Economics 106-113. Similar analyses can also be found in P. Gleadle et al., 'Restructuring and innovation in pharmaceuticals and biotech: The impact of financialisation', (2014) 25 Critical Perspectives on Accounting 67-77.

Nonetheless, CADE is concerned about the challenges to competition law and enforcement posed by new technologies and is developing studies to identify potential limitations of the current legal framework as well as of the analytical and enforcement tools.

RU The FAS Russia does not see necessity to change the objective of competition regulation. However, enforcement practice in relation to digital companies showed that there is a need to amend the current antimonopoly legislation in order to be able to reply to the challenges of the digital world. The FAS Russia prepared the fifth anti-monopoly package, which contains significant number of provisions devoted to digital economy. It concerns introduction of the new definitions, adding criteria of dominant position of the platforms, adding consideration of data ownership when analysing the market, empowering the FAS Russia with the function to impose a remedy in the form of providing non-discriminatory access to data and establishing Trustee for monitoring compliance of the economic entity with the Ruling.

CN The basic framework and principles of the existing Anti-Monopoly Law are sufficient to deal with the competition caused by the digital economy. The Anti-Monopoly Law protects fair competition in the market, which means that all operators are equal before the law. The Internet sector is also regulated under the Anti-Monopoly Law. Any operator that violates the Anti-Monopoly Law must accept the investigation of the national competition authorities and assume corresponding legal liabilities. The State Administration for Market Regulation, responsible for the unified anti-monopoly law enforcement in China, attaches great importance to the competition in the new economic field. The State Administration supervises the development of emerging fields such as the Internet according to the principle of inclusiveness, protects fair competition in the market, and provides an inclusive development atmosphere for new Internet formats and new operation models. It is necessary to fully utilise market mechanism, enhancing the role of innovation in driving the Internet industry; it is also necessary to improve the Internet industry's regulatory system, working synergistically with relevant departments, strengthening market surveillance in accordance with the law, effectively regulating the competition of platforms, investigating the alleged anti-competitive conduct, preventing the formation of industry monopolies and market barriers, protecting the legitimate rights and interests of consumers and the public interests, and guiding the healthy and orderly development of the Internet industry.

ZA The current competition Law is adequate. However, the challenges mentioned above indicate that a process of reviewing the border regulatory regime is required if South Africa is to catch up with the shifts to the digital age. Challenges faced by South Africa include concerns raised across several sectors about the fact that the broader regulatory framework in many cases does not apply to new, disruptive technology, which gives these firms an unfair competitive advantage over regulated incumbents. For instance, traditional metered taxis have raised the concern that area restrictions and price regulation applied to their business model is not applied to e-hailing firms,

placing the traditional model at a competitive disadvantage. Public and FTA broadcaster licensees subject to local content requirements express concerns that streaming services are not licensed and therefore not subject to the same regulations, and that their advertising revenue base is being rapidly eroded by Facebook and Google.

What appears to be lacking is the understanding of the tools used by digital actors in competing with one another, in setting prices, in excluding other players from the market by way of foreclosure. From the cases investigated thus far, it appears that the Commission is left behind in terms of understanding the competition dynamics in the digital markets. Thus, it appears that what needs to change or improve is mainly the tools for identifying competition issues as the traditional methods do not seem to be working well in digital markets.

Source: BRICS NCAs Questionnaire

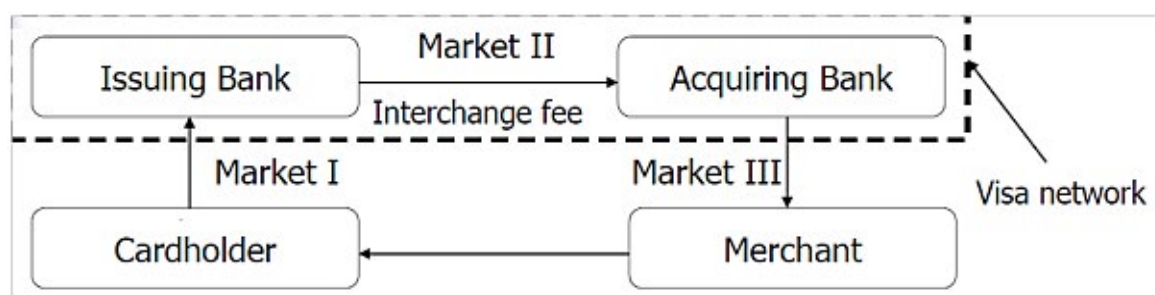

Whichever option (or options) from the above is chosen, there are adjustments that need to be made in order to take into account the specificities of the digital economy. Some of them may directly concern all options, such as for instance network effects and tipping or leverage points that may change the way we think about the need to preserve the competitive process (option iv) or promote innovation (option v). Personalisation and cybernetics may have effects as to the conceptualisation of consumer choice (option iii). However, in view of the importance given to price competition in contemporary competition law and economics analysis, it would be good to focus the specific welfare standard under dimensions (i) and (ii). Two related changes brought by digital competition are of particular relevance here. First, it is quite frequent that products may be distributed for 'free' at one side of the platform, this meaning that consumers are not charged positive prices, the products being sold at zero-prices, or even it is possible that consumers receive a reward (they are charged a positive price). Hence, it is more complex to assess the consumer welfare effect or consumer surplus effect in these markets, without also taking into consideration other parameters of competition (such as quality and variety). Second, the multisided nature of platforms renders this static and focused analysis of effects on a specific relevant market rather inconclusive. Anabelle Gawer notes the 'changing roles' of agents in these multi-sided platforms, as it is possible that '(w)hile end-users "consume" the service (search, social networking) offered by these platforms, they also constantly "feed", individually and collectively, their personal data into these platforms (as expressed by the items they search, their location, their preferences as revealed by previous queries, and their personal connections data), thereby providing the very data upon which these platforms draw upon to deliver their services' (akin to input suppliers)⁶³⁶. As it is imaginatively explained by Kate Crawford and Vladan Joler, '[...] the user is simultaneously a consumer, a resource, a worker and a product'⁶³⁷.

636 A. Gawer, Bridging differing perspectives on technological platforms: Toward an integrative framework, (2014) 43 Research Policy 1239, 1243.

637 Kate Crawford and Vladan Joler, Anatomy of an AI system: The Amazon Echo As An Anatomical Map of Human Labor, Data and Planetary Resources, AI Now Institute and Share Lab, (September 7, 2018), available at <https://anatomyof.ai/>.

There is no need to focus on an advertised-based platform in order to gauge the complexity of implementing the consumer welfare standard in the digital era of multi-sided platforms. We will use the example of a 'transaction platform, that of four-parties payment system, such as Visa or Mastercard (Figure 4.3.).

Figure 4.3.: A four-parties payment system platform

Source: Author's compilation

As it appears from Figure 4.3., there are three markets, one between networks and merchants (Market III), the other one between networks and cardholders (Market I). One may also identify market II, as acquiring and issuing banks set an interchange fee for each transaction, but we do not focus on this market right now as it is managed by the platform (Visa, Mastercard) and creates competition law problems of its own. The payment system faces competition from rival network (for instance Visa competes with MasterCard, Amex, Union Pay. Assume that each network charges a fee to a merchant in market III if a transaction is routed through that network. Each network also pays a 'reward' to cardholders to induce them to use that network and increase demand (sales) in market I. Rewards to cardholders are not sold in market III but have the effect to shift upwards demand in market I. In a competitive environment, merchants are allowed to 'steer' consumers to cheaper payment networks by providing monetary and non-monetary incentives. However, if a digital platform restricts price competition in market III by not allowing merchants to 'steer' consumers to other payment systems or to disclose the transactions' costs to cardholders and provide incentives (including monetary incentives) to cardholders to use cheaper payment cards, this may constitute *prima facie* a restriction of competition. The anti-steering rule may result in higher fees to merchants than otherwise, and clearly harms the merchants.⁶³⁸ The restriction of competition likely results in an increase in retail prices paid by all consumers, including those paying cash. The application of the consumer welfare standard requires a complex design which would enable competition authorities to take into account all the possible consumer harms, but also possible benefits to consumers. But these are many: one may refer to the harm to the merchants, consumers of market III, or to the harm of cash-paying merchants' customers, who may be considered as indirect consumers downstream market III, on which the merchants may pass the higher fees. There is however consumer ben-

638 For a detailed discussion, see F. Ducci, Out-of-Market Efficiencies, Two-Sided Platforms and Consumer Welfare: A Legal and Economic Analysis, (2016) 12(3) Journal of Competition Law and Economics 591.

efit in market I, as because of the anti-steering rules, and the possibility to increase its fees, the payment system may afford to reward cardholders with positive prices, for instance travel or shopping rewards etc. A competition analysis focusing on consumer welfare will need to decide (i) which market will serve as the main unit of analysis of consumer welfare, or (iii) to balance costs and benefits for the consumers affected in all markets. This may prove a rather difficult and resource consuming task, that would also require the possibility for out of relevant market efficiencies to outweigh consumer harm in another market.

4.2.2. Should competition law take into account the broader social cost of restriction of competition in the digital economy, and can this be done?

One may envisage the possibility that competition law may intervene in situations in which the power held by digital platforms or other digital gatekeepers and the restriction of competition in the digital economy, which result from the exercise of this power, produces broader social costs than just a cost to consumer welfare. These broader aims for competition law intervention may be considered as economic or political, to the extent that one defines economic as narrowly concerned with consumer surplus and economic efficiency. One needs however to also take into account the broader political objective to keep the Internet free from all, state or corporate, gatekeepers, which is an intrinsic characteristic of the Internet architecture that emerged from the international consensus in the early 1990s. This broad international consensus on a decentralised trans-national architecture of the Internet, most norms and principles governing protocols and standards in this network of networks deriving largely from a bottom up process⁶³⁹, may be jeopardised by the regulatory role of a handful of digital platforms. These concerns provide the philosophical background that justify the consideration of the broader social costs of the restrictions of digital competition than those encompassed by the narrow aim of consumer welfare.

Box 4.2. Social costs of the digital transformation

BR The digital transformation is a very dynamic process with positive and negative impacts in terms of social costs. Regulatory and legislation authorities have to monitor closely these impacts, updating legal and regulatory framework when necessary, in order to minimize negative impacts.

RU Today all the public authorities are engaged (within the scope of activity of every of them) to development of digital environment and creation of regulatory framework adequate for the ongoing transformations.

Source: BRICS NCAs Questionnaire

⁶³⁹ Such as the end-to-end design principle, according to which application-specific features reside in the communicating end nodes of the network, and not in intermediary nodes, such as the router, which establish the network, or the separation of the upper and lower layers with the TCP/IP protocol serving as a portability layer.

4.2.2.1. Income and wealth distribution

There are certainly many causes that could explain the recent rise in poverty and inequality: the globalization of production, the erosion of collective bargaining systems, the continued drop in real wage values, tax evasion or unfair tax systems. However, it is increasingly accepted that market power may be a significant source of both inefficiency *and* inequality. Joseph Stiglitz notes that “today’s markets are characterised by the persistence of high monopoly profits”⁶⁴⁰. He also argues that “policies aimed at reducing market power can accordingly play some role in the reduction of inequality”, although he remains careful of setting this as an explicit aim of competition law⁶⁴¹. Other economists have been equally vocal on the need for a robust competition law and policy against inequality⁶⁴². Is increasing economic concentration leading to higher degrees of inequality of wealth? This may be a difficult question to answer in view of the overall tendency of wealth concentration that has been observed during the twentieth century and at least part of the nineteenth century⁶⁴³, and according to more recent studies, apparently since the fourteenth century⁶⁴⁴, although one should note that there are various measurement and data related difficulties for such research endeavours.

The effects of concentration on the unequal distribution of wealth may, however, be linked as in the “Age of secular stagnation”⁶⁴⁵ and intense financialisation, return to capital exceeds economic growth, the result being that rentiers or senior executives, which form the bulk of the richest 1% of the population, see their share of total wealth increase. One may also rely on empirical evidence linking higher concentration following mergers to higher prices⁶⁴⁶, and evidence showing that in the ‘winner-take-most’ competition of digital markets, where ‘superstar firms’ command growing market shares and

become highly profitable, one may observe a larger decline in labour's share⁶⁴⁷, which has obviously an impact on economic inequality.

Box 4.3. how should BRICS NCAs address digital platforms where 'winner takes most'?

BR In many cases, the "winner takes most" situation is the equilibrium of some digital markets. In such cases, attempting to superimpose a different market structure (say, one in which all firms have approximately equal market shares) may be counterproductive and inefficient. On the other side, it is necessary to prevent the misuse of market power. Therefore, finding the right balance is essential for promoting innovation and protecting consumer welfare in the fast-moving environment presented in digital markets.

RU The experience of the FAS Russia shows that the significant market power of the digital platform could be addressed with the remedies of providing access to data or technological transfer to the market players which could hypothetically be competitors.

CN The digital platform usually involves multi-sided markets, which is partially or completely free. Compared with the traditional industry, it has the characteristics of network effects and locking effects. Therefore, the competition authorities face challenges in market definition, competition assessment, remedies, and other aspects in the cases involving digital platforms. This requires the authorities, on the basis of further in-depth research, to adjust and employ flexibly the traditional concepts and tools of Anti-Monopoly Law according to the specific circumstances of the case concerned.

ZA South Africa's experience in digital markets is limited. However, depending on how the challenges presented by digital markets are addressed on a case-by-case basis, South Africa may either face increasing competitive, contestable markets in the future, where efficiency and continuous innovation prevail, or end up in situations of 'winner takes most.' Hence, each case needs to be assessed on its merits. From the mergers' perspective, the access condition with no room to discriminate should always be imposed. The difficulty will be to understand how the merging parties can use the sophisticated digital tools to circumvent the conditions.

Source: BRICS NCAs Questionnaire

To the extent that competition law regimes may integrate 'fairness' concerns and not focus on consumer surplus, or more broadly consumer welfare, it is possible that they may scrutinise more carefully mergers or conduct that may reduce competition and maintain or increase economic concentration in the market.

More concretely, competition authorities usually employ an error cost framework in their analysis over the need to intervene, or not on a specific market, following the

647 D. Autor, D. Dorn, L. Lawrence, F. Katz, C. Patterson & J. Van Reenen, Concentrating on the Fall of the Labor Share, (2017) 107(5) American Economic Review 180.

identification of a market failure resulting from the existence or the exercise of market power. Social costs can be of two sorts: ‘substantive costs’ (error costs)⁶⁴⁸ and ‘procedural costs’, also called costs of ‘error-minimizing procedures’ or decision costs)⁶⁴⁹. There is a negative correlation between these two forms of costs, as in order to evaluate accurately the costs or benefits of specific conduct and thus minimize substantive errors (false positives or false negatives), which are costly, one would need to spend more time and resources gathering evidence and assessing it, thus increasing decision costs. False positives (or type I error) occur when the decision maker finds violations although the conduct did not harm competition, while false negatives (or type II error) occur when the decision maker does not find violations although the conduct harmed competition.

For instance, an approach requiring the identification and analysis of all possible effects of a conduct on consumer welfare would have limited the likelihood of error costs, but at the same time increase the likelihood of decision costs (e.g. costs of information gathering and processing). Decision makers employ a sequential information gathering process in order to reduce information and, more broadly, decision costs, while of course aiming to minimize the occurrence of substantive errors.⁶⁵⁰ The decision to acquire more information is a trade-off between two types of costs: ‘error costs on the one hand’, that is the decision maker may mistakenly identify a pro-competitive practice as being anticompetitive or the opposite, and information or decision costs on the other.⁶⁵¹ This trade-off is done incrementally, at each level of this sequential assessment.

The assessment of costs involves some value judgment on the acceptability of type I or type II errors. These costs are not just administrative (the cost of arriving to a decision and implementing it) or substantive (the cost of an under-inclusive or over-inclusive rule with regard to the coverage of the rule on the basis of its statistical significance – how well the results represent the occurrence of false positives or false negatives in practice), but also the broader social costs of such errors. Indeed, it is possible that for several reasons competition law regimes may provide more weight in terms of social cost to false negatives than to false positives. The fact that digital markets are characterised by network effects, and the realisation that positions of power may be quickly entrenched

648 These are often the focus of competition law and economics commentators since the early 1970s and constitutes one of the principal contributions of the Chicago school of antitrust law and economics. As it is explained by J. Baker, *Taking the Error out of the ‘Error Cost’ Analysis: What’s Wrong with Antitrust Right*, (2015) 80(1) *Antitrust Law Journal* 1, 4, ‘(t)hat framework was first employed in the law and economics literature by Richard Posner during the 1970s and introduced into mainstream antitrust scholarship by Paul Joskow and Alvin Klevorick in 1979. Modern antitrust commentators often refer to Frank Easterbrook’s adoption of the framework in a widely-cited article published in 1984 but the idea is older: R. A. Posner, *An Economic Approach to Legal Procedure and Judicial Administration*, (1973) 2 *Journal of Legal Studies* 399; P. L. Joskow & A. K. Klevorick, *A Framework for Analyzing Predatory Pricing Policy*, (1979) 89 *Yale LJ*. 213; Frank H. Easterbrook, *The Limits of Antitrust*, (1984) 63 *Texas Law Review* 1.

649 Alex Stein, *Foundations of Evidence Law* (OUP, 2005), 1. One may also expand this category to ‘transaction costs’, which costs go beyond the costs of adjudication and information gathering but also include the costs of ‘uncertainty about legal rules’, which ‘chills beneficial conduct or means that those rules fail to deter harmful conduct’: J. Baker, *Taking the Error out of the ‘Error Cost’ Analysis: What’s Wrong with Antitrust Right*, (2015) 80(1) *Antitrust Law Journal* 1, 5.

650 C Frederick Beckner III and Steven C Salop ‘Decision Theory and Antitrust Rules’ (1999) 67 *Antitrust Law Journal* 41, 43.

651 *Ibid.*, 46.

after a tipping point and provide possibilities to some economic actors to leverage their powerful position in other markets, and thus to affect inequality may lead competition authorities to weigh more as cost of error false negatives than false positives, and consequently take a more pro-active approach, eventually relying on some form of implementation of the principle of precaution in competition law⁶⁵². The level of statistical significance is often set by the statistician in light of the acceptable rate of false positives. However, this issue is not related to substantive significance that measures the real social cost of false positives or false negatives, from a policy perspective. In order to assess substantive significance it is important to specify and examine the 'loss function' (utility loss associated with an estimate being wrong as a function of the difference between the estimated value and the real value), then, by what scale a number is large or small for the specific policy purpose and, finally, to perform a cost benefit analysis that will include the cost of this loss function⁶⁵³. Similar consideration may also take place when performing the error cost analysis with as only focus consumer welfare. One may also criticise the error cost framework altogether, in view of the rather rapid development of technology and the limited knowledge of competition policy makers and competition authorities as to the real impact of their decisions in the future. In this case, we can refer to a different mostly descriptive model relying on Bayesian statistics, where probabilities are always beliefs, rather than classical statistics where probabilities are objective. In the Bayesian analysis, the starting point is a 'prior belief' about the state of the world and then evidence changes those beliefs so that, having incorporated the evidence, the end point is a 'posterior belief' about the state of the world⁶⁵⁴. The challenge to Bayesian statistics has always been that the prior beliefs may affect the resulting posterior belief whereas, perhaps in an ideal world, the evidence alone would drive the conclusion.

4.2.2.2. Privacy

Breaches of privacy or data protection, facilitated by the use of Big Data and sophisticated computer algorithms, may affect millions of people and, depending on the purpose, even compromise the democratic process.⁶⁵⁵ The debate over the interaction of

652 See, for instance, the approach of the EU Court of Justice in Case C-52/09 *Konkurrenverket v TeliaSonera Sverige AB* [2011] ECR I-527, para 108, where the CJEU noted that '(p)articularly in a rapidly growing market, Article 102 TFEU requires action as quickly as possible, to prevent the formation and consolidation in that market of a competitive structure distorted by the abusive strategy of an undertaking which has a dominant position on that market or on a closely linked neighbouring market, in other words it requires action before the anti-competitive effects of that strategy are realised'.

653 Deirde Mc Closkey & Stephen Ziliak, *The Cult of Statistical Significance* (Univ. of Michigan Press, 2007), 97, who also note at 5 that '(a)ccepting or rejecting a test of significance without considering the potential losses from the available courses of action is buying a pig in a poke. It is not ethically or economically defensible'.

654 Specifically, Bayesian statisticians consider that an investigator will begin with a 'prior belief' about a given hypothesis, $P(h)$. Evidence may then allow those beliefs to be updated to give 'posterior beliefs' describing the likelihood of the hypothesis given the evidence, $P(h|e)$. Bayesian statisticians use Bayes Theorem to calculate their posterior beliefs using the formula $P(h|e) = P(e|h) * P(h)/P(e)$ where $P(e)$ denotes the probability of observing the evidence we see; $P(e|h)$ denotes the probability of observing the evidence given the hypothesis h ; and $P(h)$ is the prior belief

655 J Drexler, 'Economic Efficiency versus Democracy: On the Potential Role of Competition Policy in Regulating Digital Mar-

privacy and competition law has been particularly vivid in the EU, as well as in its Member States, in view of the ‘constitutional’ protection of privacy,⁶⁵⁶ and the existence of an elaborate system of data protection.⁶⁵⁷ The discussion has since moved on to all other jurisdictions, with the enactment of legislation protecting privacy⁶⁵⁸ and the development of data protection regulation⁶⁵⁹. In recent years, the digital sector has attracted the attention of competition authorities and regulators involved in data protection.⁶⁶⁰ Competition authorities have also looked to these questions when exploring the changes brought by platform competition.⁶⁶¹

One of these issues is whether merger control should take into account the fact that access to personal data may constitute an important source of market power⁶⁶². Competition authorities are also increasingly active in data markets, reviewing exclusionary conduct involving (personal) data, but also examining the possibility of applying the provisions on abuse of a dominant position against privacy breaches, discrimination and exploitative contracts, which may be facilitated by control of big data, companies interchanging individualized offers on the basis of the information they acquire on individuals’ willingness to pay through their past browsing history or other personalising factors; this enables them to charge different prices to various customers for homogeneous products (online personalised pricing).⁶⁶³ Certain competition authorities have found that these practices may represent an abusive imposition of unfair conditions on users,

kets in Times of Post-Truth Politics’ in D Gerard and I Lianos (eds), *Competition Policy: Between Equity and Efficiency*, (forthcoming, CUP 2019).

656 Article 7 of the Charter of Fundamental Rights lays down the right to respect for private and family life, home and communications, protecting the individual primarily against interference by the state.

657 Article 8 of the Charter of Fundamental Rights recognises the protection of personal data as a separate right, which goes beyond simply protecting against interference by the state, but entitles the individual to expect that his or her information will only to be processed, by anyone, if however this processing is fair and lawful and for specified purposes, that it is transparent to the individual who is entitled to access and rectification of his/her information. The EU has adopted Regulation (EU) 2016/679 General Data Protection Regulation [2016] OJ L 119/1 the protection of natural persons with regard to the processing of personal data and on the free movement of such data, which applies from 25 May 2018. Its scope is significant and wide-ranging.

by limiting their ‘informational self-determination’⁶⁶⁴. These practices raise the question of the interaction between competition law and other social and technical regulatory regimes protecting consumers or personal data.

This is not the only available integration strategy for privacy concerns. A number of authors have put forward various strategies in order to ensure the commensuration of privacy concerns within the competition law toolbox, such as assessing privacy as an element of product quality,⁶⁶⁵ an element of consumer choice, or as a ‘non-monetary price’.⁶⁶⁶ Noting the ‘privacy paradox’, that is that consumers often state different preferences than those they actually reveal by their behaviour on the marketplace, these authors argue for the adoption of different methodologies than the price-based revealed preferences model of valuation, which has in any case difficulties to work in the context of a ‘free’ product not subject to monetary evaluation,⁶⁶⁷ as is often the case in these multi-sided markets.⁶⁶⁸ These approaches have in common that they treat privacy as a parameter of price competition⁶⁶⁹, even if this does not take a monetary form⁶⁷⁰.

In their effort to establish some form of commensuration that would enable balancing, some authors explore alternatives to the traditional consumer welfare standard:

- (i) a ‘*broad* consumer welfare standard’, which will indirectly take into account non-economic interests, to the extent that these are directly related to the relevant market and accrue to the consumers of these markets, in a similar vein than the approaches explored above regarding the integration of privacy;
- (ii) an ‘inclusive welfare standard’ that would take non-economic interests directly into account even if these do not affect the consumers of the relevant market, for instance through the consideration of some other unspecified aggregation method and

- (iii) a ‘capability approach’, that would not rely on a welfarist standard.⁶⁷¹ The last approach relies on the theoretical framework put in place by Amartya Sen, focusing on ‘well-being’, rather than welfare.⁶⁷² This calls for a new metric enabling some degree of commensuration and interpersonal comparison relying on the concepts of ‘functionings’ and ‘capabilities’. ‘Functionings’ are ‘beings’, such as being well-nourished, being undernourished, being safe, being able to participate to social and economic activities, but also being in bad health, and ‘doings’, such as voting in an election, travelling, eating to your hunger, consuming fuel to get warm, but also taking illicit drugs. For instance, consuming a lot of fuel might be considered as a positive thing for someone taking a growth perspective, while a bad thing for an environmentalist or from a sustainable growth perspective. Capabilities constitute a person’s real freedoms or opportunities to achieve these specific functionings. Contrary to the welfarist perspective, in the capabilities approach social welfare is not seen as ‘a function of the person-specific distribution of each commodity’, but ‘as a function of the combination of everyone’s functioning vectors (or of everyone’s capability sets)’.⁶⁷³

The legal status of the right to privacy, which is recognised in some jurisdictions,⁶⁷⁴ as well as the development of specific legislation to ensure data protection,⁶⁷⁵ should also provide the evidence of the hypothetical extended preferences of consumers/citizens to have their personal data protected, even if in practice their choice on the market may reveal that they are ready to be lured to sacrifice it for some other immediate gratification/benefit (e.g. free search). Their behaviour as revealed by their choices in the market sphere may not constitute evidence of their true preferences, as it cannot be excluded that their behaviour may have been manipulated by a more powerful actor. It would therefore make sense to also rely on evidence of these extended preferences by looking to the rights and duties provided for in legal system where all actors are, at least formally, equal.

4.2.2.3. Fairness and complex equality

There is a widespread perception in public opinion and among commentators, that the small number of digital platforms and the resulting global economic concentration may have important implications on the political process, further undermining the autonomy of the political and cultural order vis-à-vis the economic order. For example, there are studies documenting how corporate lobbying is directly related to firm size⁶⁷⁶ and

671 [R Claassen and A Gerbrandy, ‘Rethinking European Competition Law: From a Consumer Welfare to a Capability Approach’ \(2016\) 12\(1\) Utrecht Law Review 1.](#)

evidence that large digital platforms are important contributors to the lobbying industry⁶⁷⁷. There is also evidence that the Big Tech industry has led an effort to influence academic writing in the area of competition law and policy⁶⁷⁸. Overall, the greater the market power enjoyed by firms, the more they have “both the ability and the need to gain political power”⁶⁷⁹. This has led a number of authors to argue that competition law should have a role in order to ensure the autonomy of the political and social sphere, on the basis of the principle of ‘complex equality’⁶⁸⁰. According to this view, economic power may lead to political and cultural power, not only in the sense that it will generate some form of resource dependence, measured by the ability to raise prices profitably on a relevant market, or the ability to exercise superior bargaining power, in the specific social sphere (monopoly), but also because it will influence the options available for each individual agent in other spheres of social activity. Dominance will therefore challenge the autonomous distribution criteria applying in the various social spheres.

The existence of autonomous distributive criteria requires that no citizen’s standing in one sphere or with regard to one social good can be undercut by his standing in some other sphere, with regard to some other good. ‘Complex equality’ aims to narrow the range within which particular goods are convertible and to preserve the autonomy of distributive spheres. Individuals interacting with digital platforms in the context of an on-line market transaction may use their algorithmic power to gain power in other spheres of social activity, which through lobbying they may later convert in economic power, as rent seeking and lobbying constitute the second most important driver of firms’ profitability.⁶⁸¹ Why should we not consider this multi-dimensional nature of competition, for

679 L. Zingales, *Towards a Political Theory of the Firm*, NBER Working Paper No. 23593 (July 2017). Of course, other (cumulative or alternative) explanations for market concentration have been put forward: (i) the rise of IT and important expenses in developing IT systems (see, J.E. Bessen, *Information Technology and Industry Concentration*, (December 1, 2017). Boston Univ. School of Law, Law and Economics Research Paper No. 17-41. Available at SSRN: <https://ssrn.com/abstract=3044730> finding that industry concentration – the share of revenue captured by the top firms in a sector – is largely explained by the adoption of IT and that IT systems appear to play a major role in the recent increases in industry concentration and in profit margins, more so than a general decline in competition); (ii) the importance of investments in intangibles, such as brands, software, employee training, management (see J. Haskel & S. Westlake, *Capitalism without Capital* (Princeton Univ. press, 2017); (iii) the rise of “superstar firms” or “superforcasters” which are able to take advantage of technology, including Big Data and artificial intelligence, in understanding better than “standard” firms the competitive game) (see on “superstar firms”, D. Autor, D. Dorn, L.F. Katz, Ch. Patterson, J. Van Reenen, *The Fall of the Labor Share and the Rise of Superstar Firms*, NBER Working Paper No. 23396 (May 2017). For a comparative discussion of various causes, see J.E. Bessen, *Accounting for Rising Corporate Profits: Intangibles or Regulatory Rents?*, (November 9, 2016). Boston Univ. School of Law, Law and Economics Research Paper No. 16-18. Available at SSRN: <https://ssrn.com/abstract=2778641> .

680 For a discussion of this principle, see M. Walzer, *Spheres of Justice: A Defense of Pluralism and Equality* (Basic Books, 1983).

681 JE Bessen, ‘Accounting for Rising Corporate Profits: Intangibles or Regulatory Rents?’ (2016) Boston Univ School of Law.

the simple reason that the current version of competition law only focuses on price and output competition?

Indeed, digital platforms have become the central nervous system of modern capitalist value generation. Some jurisdictions, like the EU, have been quite concerned by the transformation of these digital platforms to important gatekeepers for various economic activities in the digital economy⁶⁸², and of their ability to leverage their economic power (resulting from the control of resources such as Big data, algorithms and Artificial Intelligence, on which the new model of economic production depends) in various domains of activity, including the capture of an even higher percentage of the total surplus value of the value chain⁶⁸³. Concerns over the fact that control of (personal) data by these digital platforms may affect privacy⁶⁸⁴, but also more generally the political process⁶⁸⁵, thus leading to the emergence of a dominant position over a dominant social good (the dominant social good in question being information) have been quite prominent in the current debate over the economic (and political/cultural) power of BigTech.

4.3. The changing competition game

New technologies require important investments and fixed costs for their developments. This may lead to increasing returns to scale, the average cost of producing output being smaller at larger levels of output. From the demand side, consuming such technologies often leads to network effects, as use of a product or service by any user increases the product's value for other users (sometimes even all users). In other words, the value of the product to one user is positively affected when another user joins and enlarges the network (positive network externalities)⁶⁸⁶. Furthermore, an additional user

[Law and Economics Research Paper No 16-18<ssrn.com/abstract=2778641>](https://ssrn.com/abstract=2778641) accessed 26 October 2018.

682 See, EU Communication on digital platforms of 25 May 2016 (COM(2016)288 final) 12, noting that “(a)s online platforms play an increasing role in the economy, the terms of access to online platforms can be an important factor for online and offline companies. For SMEs and micro-enterprises, some online platforms constitute important, sometimes the main, entry points to certain markets and data”.

683 This explains the recent focus of competition authorities in Europe on leveraging practices, with the aim to ensure the “equality of opportunity” of economic operators (see, European Commission, Case AT 39.740 – Google Search, paras 332 & 334), as well as recent ideas to regulate from a fairness perspective platform to business relations (see, Inception Impact Assessment, Fairness in Platform to Business Relation, Ares(2017)5222469, available at https://ec.europa.eu/info/law/better-regulation/initiatives/ares-2017-5222469_en).

684 See, European Data Protection Supervisor, Privacy and competitiveness in the age of big data: The interplay between data protection, competition law and consumer protection in the Digital Economy (March 2014); Autorité de la Concurrence & Bundeskartellamt, Competition Law and Data (May 16, 2016); US FTC, Big Data – a Tool for Inclusion or Exclusion? (January 2016). Some public authorities have also looked to these questions when exploring the changes brought by platform competition: European Commission, Online Platforms and the Digital Single Market Opportunities and Challenges for Europe, COM/2016/0288 final; House of Lords, Online Platforms and the Digital Single Market, HL Paper 129 (2016); OECD, Big Data: Bringing Competition Policy to the Digital Era, DAF/COMP(2016)14.

685 See, for instance, the debate about “fake news” presumably promoted by some digital platforms as being an “antitrust problem”: S. Hubbard, ‘Fake News Is A Real Antitrust Problem’, (2017) Competition Policy International; S.P. Sacher & J.M. Jun, ‘Fake News is not an Antitrust Problem’ (2017) Antitrust Chronicle.

686 This positive feedback loop may work in reverse and in case the technology/product fails to reach a critical mass of us-

of a search engine may increase the quality of search provided by this search engine, therefore benefitting all users, in view of the additional queries that this may direct to the search engine and consequently the increase in the stock of data/ information the specific search engine disposes about users and their preferences which can help search engines to offer better search services to all consumers (learning-by-doing effects). These positive feedback loop mechanisms explain why these markets are 'tippy' and are characterized by 'winner takes it all' competition. For instance, there might be fierce competition to conquer a market share advantage over rivals, with regard to the specific technology or standard applying in the industry, as the market may switch almost completely to the winner (competition for the market).

Digital firms (and in particular digital platforms) generate profit in two principal ways:

- (i) they may exploit, better than conventional firms, the willingness to pay of their users, either by better understanding through data harvesting and personalisation the willingness to pay of their various market sides (in case the platform acts as an intermediary), thus extracting a higher surplus for their 'matching', or by increasing their willingness to pay for the platform itself adding new functionalities and features and developing an ecosystem of complementary products, which increase the value of the platform'
- (ii) they may adopt value capture strategies that aim to extract more surplus value from their ecosystem, for instance by capturing 'value as a portion of the sale of every complementary product or service sold for the platform, including its complements they build themselves'⁶⁸⁷.

4.3.1. Financialisation and the re-interpretation of competition: implications for the digital economy

The recent discussion over the implementation of competition law in the digital economy has mainly focused on issues of access to data, interoperability of technologies and protection of final consumers from exploitation in product markets⁶⁸⁸. The starting point of the analysis provided and the recommendations take the traditional perspective of product market competition, with the additional emphasis put on data, as the most important input in the digital economy. This is of course an important dimension of competition, but hardly the most significant one, if one focuses on the process of value generation and capture in the digital economy, which is, as we described marked by the

ers, it may fall into a 'death spiral' and ultimately disappear: see H Varian, Use and Abuse of Network Effects (September 17, 2017). Available at SSRN: <https://ssrn.com/abstract=3215488>.

characteristic of futurity. Firms do not only compete in the product market dimension, the geographical boundaries of markets being to a certain extent expanded with the emergence of the Internet, but in the today's financialised economy, probably the most important locus of competition is capital markets. We will first describe the process of financialisation, before explaining how this could be relevant for our effort to understand competition in the digital era.

4.3.1.1. Financialisation and the rise of financial capitalism: implications for the digital economy and competition

The process of financialisation of the global economy has been described as a recurrent trend affecting a number of markets⁶⁸⁹. There has been a transformation of corporate control and behaviour since the 1970s. With the development of the multiproduct firm, in which managers sought to spread risks across various product lines in order to achieve greater profitability and to grow through mergers financed by leveraged buy-outs, private equity investing, financed by junk bonds and other innovative financial techniques, has driven an increase in the level of corporate debt. The financialisation of the modern corporation has been a marked feature of this evolution. This process led to an important increase of the profits of the finance sector (finance, insurance and real estate) from barely 10% to approximately 45% of total corporate profits between 1950 and 2001, while the profits of the manufacturing sector dropped during the same period⁶⁹⁰. It also led to a significant increase in the share of financial assets held by the non-financial sector of the economy and an increased importance of financial revenue for nonfinancial businesses⁶⁹¹. This period coincides with the prevalence of the shareholder value principle⁶⁹², which dominated corporate governance discourse since the 1970s, and the subsequent focus on short-term share price⁶⁹³. The shareholder primacy principle changed managerial priorities from that of maximising growth by re-investing corporate savings in the long-term productive potential of the corporation (the principle of 'retain and re-invest') to that of maximising stock value through extensive buybacks of corporate stocks (share repurchase) in order to inflate stock prices as the resulting artificial scarcity of shares boosts their value⁶⁹⁴.

694 W. Lazonick, *Profits without Prosperity*, *Harvard Business Review* (September 2014), available at <https://hbr.org/2014/09/>

Disciplined by a corporate market for control dominated by financial interests, in particular institutional investors, corporate managers became increasingly aligned with the interests of shareholders, and adopted strategies aiming to increase the price of their corporate stocks. They downsized their corporations (in particular cutting labour costs) in order to create short term shareholder value and distributed the freed up corporate revenues to financial interests, particularly shareholders, instead of re-investing them in the corporation (the principle of 'downsize and distribute')⁶⁹⁵.

An important facet of the financialisation movement has been the increasing leveraging of corporations through debt and other hybrid financial instruments and consequently their dependence on the investments of some institutional investors which increasingly now own shares in publicly listed companies, displacing ownership by physical persons⁶⁹⁶. Lazonick and O' Sullivan have highlighted how 'the rise of the institutional investor as a holder of corporate stocks encouraged top managers to align their own interests with external financial interests than with the interests of the productive organizations over which they exercised control'⁶⁹⁷. This literature has also shown how financial profits (mainly interest and dividend income as well as realised capital gains) form a significant part of corporate cash flow, this growing financialisation being inversely related to fixed investment⁶⁹⁸. The abandonment of the 'retain and re-invest' principle in favour of buybacks is indeed considered as one of the main sources of the stagnating productivity since the 1980s, as the economy is 'starved' from productive investments⁶⁹⁹. The expansion of non-financial corporations into financial assets holdings shifts firm-level portfolio composition from fixed capital towards liquid financial assets (such as cash and short-term investments) and raises leveraging, in particular for larger firms which become increasingly focused on stock market performance, while unlisted smaller and medium-sized firms slowly de-leveraged their balance sheets⁷⁰⁰.

700 L. E. Davis, The financialization of the nonfinancial corporation in the post-1970s U.S. economy (2014), Doctoral Dissertations. 175, p. 44.

The rise of institutional investors constitutes an epiphenomenon of this growing financialisation of the economy. This is a quite disparate group of legal entities whose purpose is mainly to manage and invest other people's money, although this is not always the case and there are hybrid forms of equity funds in which the managing partners co-invest with the limited partners⁷⁰¹. Institutional investors include traditional financial investors, such as investment funds (in particular index funds), pension funds and insurance companies, as well as 'alternative' institutional investors, such as hedge funds, private equity funds, and sovereign wealth funds⁷⁰². The degree of engagement of these institutional investors in the competitive strategy of the corporations they invest in varies. One may contrast active hedge funds or mutual funds, with some index funds are investment funds (mutual funds or exchange traded funds) that track mechanically the performance of an index and are presumed to be 'passive' as they have little incentives to invest in the stewardship of the companies in which they are present⁷⁰³. Hence, they defer excessively to the positions of corporate managers⁷⁰⁴. Because of their 'passive' nature, they are not concerned with firm-level performance, as would normally active shareholders, but to the extent they are investing in a group of companies, they are simply concerned by the performance of their portfolio of firms, without however their internal structure and governance leading them to engage with the governance of their portfolio companies.

The institutional investor and asset management market has witnessed in recent years a significant process of concentration. Recent research has found that the 20 largest asset management firms around the globe account for 43.3% of the top 500 managers' total assets under management (AUM) and represent US\$ 93.8 trillion in 2017, the highest level of concentration at least since 2000⁷⁰⁵. 'Passive' index funds, such as BlackRock with \$6.3 trillion total AUM, Vanguard Group with \$4.9 trillion total AUM, and State Street Global with \$2.7 trillion, constitute the top three asset managers globally in 2017 (called 'The Big Three')⁷⁰⁶, followed by Fidelity, with \$2.4 trillion AUM, which does offer passive

701 S. Çelik & M. Isaksson, Institutional investors and ownership engagement, (2013) 2 OECD Journal: Financial Market Trends 93, 96.

702 Ibid.

703 Note however that passive investment does not equal passive ownership. Lots of the common ownership literature stresses how index funds do engage significantly in corporate governance activities. The crucial difference is the investment time horizon – e.g. index funds, which have very low turnover, essentially invest in perpetuity and so have long horizons and are materially interested in good governance among their portfolio companies. In contrast, a quantitative active fund may buy and sell frequently as per the recommendations of their model and so do not establish meaningful relations with the management of portfolio companies.

funds but they are just not that large⁷⁰⁷. The concentration of corporate ownership resulting from the concentration of the asset management market may lead index funds to be more actively engaged with corporate strategy and influence corporate management, either actively, for example by exercising the voting power of the shares owned by their funds, or more indirectly, by simply ‘doing nothing’. This may induce corporate management to internalise the index funds’ interests in competing firms, in view of the fact that their importance in the shareholding has risen significantly in recent years⁷⁰⁸. The rise of common ownership and the concentration of the asset management market may have considerably contributed to the loss of dynamism in the economy, the drop in productivity and the rise of firm markups⁷⁰⁹.

The spread of ICT and digitalization in all sectors of the economy has also led to the development of dedicated tech venture capital, mostly based in the Silicon Valley in the US, and concentrating in the hands of a few asset managers, with the knowledge, the network and the funds to credibly support the development of start-ups to large digital platforms at a global scale.

The combined effects of the shareholder value primacy and the rise of common ownership, as well as the subsequent concentration of asset management have important implications on the competitive strategies undertaken by the management of corporations. Together they challenge the ‘assumption of own-firm profit’ or value maximisation that has animated industrial capitalism since the 1930s⁷¹⁰, which forms part of the neoclassical theory of the corporation⁷¹¹. Subsequent literature has challenged the

Sinkinson, The Common Ownership Hypothesis: Theory and Evidence (Brookings, Economic Studies, 2019) (finding less a link between concentration in asset management and common ownership incentives than between a broader increase in diversification of investor portfolios and common ownership incentives).

710 This stems from the Fisher separation theorem stipulating that the goal of any firm is to increase its profits and present value to the fullest extent, the profit goals of the firm being completely separate from its diverse shareholders: I. Fisher, The Theory of Interest (Macmillan 1930). This principle stops the firm from caring what the shareholders’ utility function is, which is also an implication of the separation of management and control as envisaged by A. A. Berle & G. C. Means, The Modern Corporation & Private Property (Routledge; 2nd edition, 1991, first published in 1932).

711 For an interesting discussion, see H. Hovenkamp, Neoclassicism and the Separation of Ownership and Control, 2009). Faculty Scholarship. 1792. http://scholarship.law.upenn.edu/faculty_scholarship/1792.

separation theorem, finding that the turn to shareholder primacy in the late 1970s with the emergence of financialisation, and the fact that the shareholding of public corporations is less dispersed resulting from the rise in common ownership, may have multiple effects.

It may:

- (i) increase the influence of shareholders in determining the utility function of the corporations in which they invest, thus challenging one of the assumptions of the Fisher separation principle,
- (ii) it may lead shareholders not to want firm-profit/value maximisation, but instead maximisation of the value of their whole portfolio of shares in other firms present in the industry, and thus
- (iii) it may result in altering corporate managers' incentives to aggressively compete on product markets with competing firms in which the common owners also hold shares⁷¹².

These characteristics have important implications for competition law. Indeed, competition does not only take place in *product* markets (competition between products), as mainstream competition law assumes, but also in *capital* markets ('competition between capitals'). Competition becomes a struggle to lower costs per unit of output with the aim to gain more profit and market share and thus raise the rate of return of the capital invested⁷¹³. Some have also distinguished between *competition within an industry*, which forces individual producers to set prices that keep them in the game and compels them to lower costs so that they can compete effectively, thus leading to a turbulent equalization of selling prices but a dis-equalization of profit margin and profit rates, and *competition between industries*, the capital moving from one industry to another in search of higher profits, thus bringing about the equalization of profit rates between industries.⁷¹⁴

It is interesting to place the emergence of large global digital platforms in the context of the development of different forms of competition corresponding to the different stages (not varieties) of capitalism in the modern era⁷¹⁵. To some extent these global digital

714 Ibid., p 34.

715 For an interesting discussion, see B. Carbala Smichowski, Competition and Market Power: A Critical Reassessment in Light of Recent Changes, PhD thesis (Paris 13, 2018) (distinguishing different forms of competition for each period of capitalist development: 'predatory competition' (1840-1860) which corresponds to the phase of capitalism that is linked to the consolidation of the corporation as the organization carrying on the production and the delivery of goods and services; 'collusive competition' (1870-1910) linked to the need for firms facing important technological disruption brought by the second industrial revolution and the rise of patenting requiring important investments and fixed costs to control their competitive environment through explicit coordination with competitors, eventually through the first wave of M&As in view of the difficulty of forming cartels after the adoption of the Sherman Act in the US; 'constricted competition' (1920s-1945) with the development of vertical integration, product differentiation and advertising in order to manage demand, mass production, ex ante pricing etc., the dominant market structure during this period being vertically integrated oligopolies; 'Fordist competition' (1945-1970s) involving the development of industrial conglomer-

platforms have been compared to the industrial conglomerates that dominated the US and global economies from the 1950s to late 1970s. US economist Galbraith, commenting on the rise of the conglomerates, argued that they relied on industrial planning, which was necessary in order to provide the stability that the significant commitment of capital and time for the development of more sophisticated technologies required, the more technically sophisticated the product is, the more important it is for the economic entities to plan their industrial production, but also “manage demand” (e.g., through advertising), in advance⁷¹⁶. This could take several forms, one being vertical integration and different forms of contractual restraints. Galbraith coined the term of “technostructure” to refer to the main source of authority in this more technologically sophisticated part of the economy. This term did not only make reference to the management of corporations but to a broader corporate technocracy, which controlled corporate savings that were quite significant during this period and represented more than three fifths of the total of savings supplied. Indeed, most of the earnings of a corporation were not paid as dividends to stockholders, but were instead retained by the corporation and reinvested or used for wage increases, in what has been qualified as the ‘retain and reinvest’ model of the corporation.⁷¹⁷ The essence of the power held by the technostructure relied on the specialised knowledge that was necessary for the organisation of the production and sale of more sophisticated technologically products, capital and labour being relatively less important factors of production in this context. Galbraith noted a ‘shift of power in the industrial enterprise (...) from capital to organized intelligence’⁷¹⁸. Profit maximisation, which is for Galbraith ‘the only goal that is consistent with the rule of the market’, is not the goal of the technostructure, which exercises power in order to pursue other goals, and in particular the organisation’s own survival.⁷¹⁹ Price stability serves one of the main objectives of industrial planning, growth, as it facilitates ‘control and minimise[s] the risk of a price collapse that could jeopardize earnings and the autonomy of technostructure’⁷²⁰.

As explained above, the rise of financialisation led to the emergence of a different conception of the firm during the late 1970s, seen as a portfolio of activities, managed ac-

ates and multi-product firms leading to the emergence of the multidivisional form (M-firm), the production of technologically complex products requiring a more centralized organization for control, and aggressive antitrust and merger enforcement (also against vertical and conglomerate mergers) incentivizing firms’ diversification in related markets, firms making ‘profits over large quantities of standardized products instead of on large margins’ (ibid., 74); ‘finance-led competition’, which emerged as a reaction to the fact that the profit rate in the US has reached its lowest level since the beginning of World War II and led to a ‘financialised/assetized’ growth regime, leading to downsizing of conglomerates, modularization, fierce competition between international networks of vertically disintegrated firms (‘global value chains’) and the consequent ‘polarization of profit rate levels between firms’ (ibid., 80). During this period, the shareholders, in particular institutional investors, largely gained in importance with regard to workers and the firm’s management or technostructure.

720 Ibid., 241.

cording to their financial performance (in terms of rate of return on investment), rather than defined in terms of productive capabilities. A number of diversified firms were broken up in the 1980s, this movement ending the period of the 'managerial corporation' and corporations' diversification in sectors unrelated to the main activity of the corporation. It also led to the rise of the power of market finance and of debt as the main source of corporate finance. The focus shifted on short term shareholder value by the development of lean corporations (downsize) and the distribution of profits to shareholders, rather than re-investing them in the corporation (distribute). During this period the interests of institutional investors and short-term financial markets' valuations took a more prominent role and the role of technostucture and long-term planning became more limited.

Digital platforms seem to constitute a hybrid between these models of 'retain and re-invest' and 'downsize and distribute'. They are characterised by conglomerate type of expansion, marked by high diversification, often driven by merger activity in weakly related markets, rather than organic growth. For instance, Amazon started off as an online retailer of books before being vertically and horizontally integrated to being a vendor of various products and also becoming a media and entertainment company, thus competing with other media and entertainment companies whose products it also sells on its platform. Amazon has also expanded in the Internet cloud business and storage and transmission of content to consumers. Intensive merger activity has been a feature of the technology industry in recent years⁷²¹, with Google having made 214 acquisitions since the company was founded, Microsoft 189, Apple 89, Amazon 77 and Facebook 65⁷²². They also constitute eco-systems based on various forms of governance, contractual and technological (see Chapter 3). Although most of the US-based digital platforms are financialised, to the extent that large institutional investors are a prominent presence among their ownership structures (see 4.3.1.2.1.), in view of the structure of the organisation of voting rights they are more tightly controlled by their management, quite frequently their founders (see 4.3.1.2.2.). This tends to put emphasis on the long-term growth of the company, which becomes an objective as such, rather than short-term profitability. The organisational structure of the company also has some features of the M-corporation model, although financial targets may be replaced by innovation/technology targets or user base targets. Digital platforms also invest in R&D, although this is probably justified by the innovation-competition they are facing and the pressure to win the 'winner takes most' competition game. At the same time, digital platforms with a strong presence of institutional investors proceed to the distribution of dividends and stock buybacks that characterize financialised corporations (see 4.3.1.2.3.). Hence, it is possible to hypothesize the emergence of a new 'hybrid' model, which we will call 'expand and distribute'.

Competition law and economics' doctrine has not so far proceeded to a thorough analysis of how the process of financialisation of the digital economy may impact on com-

721 See, <https://www.statista.com/statistics/511172/worldwide-technology-industry-mergers-acquisitions-total-deal-volume/>.

722 See, <https://www.visualcapitalist.com/interactive-major-tech-acquisitions/>.

petition law. In our view, this should play an important role as it may shed light on the competitive strategies of firms and also their welfare effects. For instance, some authors have observed the rise of ‘digital conglomerates’⁷²³ that emerged during the last decade, mostly through a spectacular number of mergers and acquisitions that have gone through without proper scrutiny by competition authorities. These authors acknowledge that conglomerates are formed because of a quest for market power: ‘although they diversify into seemingly unrelated markets, this may indirectly increase their market power’⁷²⁴. This may either occur ‘because high degrees of diversification increase multi-market contacts, thereby facilitating (tacit) collusion between conglomerate firms’, or because ‘(c)onglomerate firms may also use cross subsidies between different lines of business to increase their market power in a given market, for example through predatory pricing’ (the “deep pocket” theory)⁷²⁵. This is not of course the only reason we witness the birth and development of digital conglomerates, as these may be formed because of excess capacity in the use of their resources (e.g. data, technology, qualified and specialised personnel), because of the existence of ‘internal capital markets that may allow new ventures to obtain funding more easily than from external capital markets’, economies of scope (in view of the existence of sharable inputs, modular design and economies in product development) and ‘consumption synergies derived by consumers when adopting product ecosystems’⁷²⁶, these factors not usually perceived by competition authorities as raising concerns. Bourreau and de Streel argue that the specific characteristics of the digital economy should nevertheless lead to a different starting point regarding these motivations for conglomerate expansion. First, they contend that ‘by making strategies of product proliferation less costly and through the control of essential inputs’ these economies of scope in product development may allow a firm to foreclose competition⁷²⁷. Second, they note the role digital platforms play as gatekeepers, which is facilitated by their presence in various markets and areas of activity that are dependent on data, and the potential impact this may have on market outcomes and welfare⁷²⁸. Third, they warn about the real motives of conglomerate mergers, which may be to pre-empt competition by killing at its birth any opportunity for a potential competitor to emerge (“killer acquisitions”)⁷²⁹.

Similar concerns over the emergence of digital conglomerates have been raised by Nobel-prize winner Jean Tirole, who raised concerns as to the adoption of possible bundling practices that may exclude new entrants from the market:

“New entrants into online markets often begin with a niche product; if it proves successful, they expand to offer a much wider range of products and services.

723 M. Bourreau & A. de Streel, *Conglomerates and EU Competition Policy* (CERRE/CRIDS, March 2019), available at <http://www.crid.be/pdf/public/8377.pdf>.

724 Ibid., 7.

725 Ibid.

726 Ibid., 9-13.

727 Ibid., 17.

728 Ibid., 18-19.

729 Ibid., 21-23.

Google began with only its search engine before it became the company we know today; Amazon started by selling books. So what matters is whether new entrants can access the market in the first place. If a newcomer has a single original product that is better than what the incumbent offers, the incumbent might want to block it from gaining even a partial foothold in the market. The incumbent will do so not to improve its short-term profits, but to prevent the newcomer from later competing in areas where the incumbent occupies a monopoly position, or to stop the newcomer from allying with the dominant firm's competitors"⁷³⁰.

A dimension that is nevertheless currently missing from the debate is the role of financial markets in providing the impetus for conglomerate expansion and the constitution of conglomerates. We have been focusing too much on digital capitalism, without comprehending that the shift towards datafication may not have had such dramatic economic and social consequences so far if it was not paired with another older shift in the global economy, the emergence of the era of financialised capitalism. In order to understand this financial dimension and incorporate it into the competition law and economics framework, it becomes important to explore the role of financialisation in general, but also in particular with regard to the emergence and expansion of digital platforms.

4.3.1.2. Digital platforms and financialisation⁷³¹

This Section explores in more detail the influence of financialisation on digital platform companies. Financialisation at the firm level entails the ascendancy of shareholder value maximisation as the guiding principle of corporate behaviour among non-financial companies.⁷³² 'Financialised' firms act to improve the welfare of their shareholders, regardless of the impact of such actions on other stakeholders, including workers or society more generally.⁷³³

A clear indication of financialisation is the amount of cash firms redistribute to their shareholders through dividends and share buybacks, at the expense of other ends such as investment in R&D or improved worker remuneration.⁷³⁴ As noted above, we may contrast financialised firms that engage in such strategies with conglomerates, which dominated the Anglo-American economies until the 1970s and behave according to a business model built on the retention and reinvestment of profits.⁷³⁵

730 J. Tirole, *Regulating the Disrupters*, (January 1st, 2019), available at www.livemint.com/Technology/XsgWUgy9tR4uao-ME7xtlTI/Regulating-the-disrupters-Jean-Tirole.html (

731 This Section was drafted with a significant contribution by Andrew McLean and the research assistance of Igor Kharitonov.

732 See L. E Davis, *The financialization of the nonfinancial corporation in the post-1970 U.S. economy* (PhD thesis, University of Massachusetts 2014).

733 See Alexander Styhre, *The Financialization of the Firm: Managerial and Social Implications* (Edward Elgar 2015).

734 See M. Mazzucato, *The Value of Everything* (Penguin 2019).

735 For example, W. Lazonick, 'Stock buybacks: From retain-and-reinvest to downsize-and-distribute' (2015) Centre for Effective Public Management at Brookings <<https://www.brookings.edu/wp-content/uploads/2016/06/lazonick.pdf>> accessed 23 May 2019.

In this section we explore whether digital platforms have become financialised or if they more closely resemble traditional conglomerates. Furthermore, we suggest the traditional demarcation between strategies of ‘downsize and distribute’ and ‘retain and reinvest’ breaks down in the context of the digital platforms and we see the emergence of a new hybrid form of capitalism characterized by strategies of ‘expand and distribute’.

Our analysis centres on the five largest digital platforms by market capitalisation: Microsoft, Apple, Amazon, Alphabet and Facebook. Overall, we report mixed results. Apple, and to a lesser extent Microsoft, appear to be financialised. In contrast, Amazon, Alphabet and Facebook appear resistant to the financialisation trend.

To build a picture of the degree of financialisation among digital platform firms, we present quantitative data on the following: (i) shareholding patterns; (ii) shareholder voting rights; and (iii) dividend, share repurchasing and R&D activity.

4.3.1.2.1. Shareholdings of Digital Platforms

The presence of institutional investor shareholdings is a necessary (but insufficient) precondition for the financialisation of a firm. Institutional investors, through concentrating the stock ownership of dispersed asset holders, strengthen the voice of shareholders.⁷³⁶ Therefore, we examine the ownership structure of Microsoft, Apple, Amazon, Alphabet and Facebook. We remark upon the overall proportion of institutional investor ownership and the identity of top shareholders, including institutional investors, insiders (executive officers and directors), or investors that are neither institutional nor insiders. First, we observe that each platform is predominantly owned by institutional investors. This is illustrated below:

Digital Platform (<i>Nationality</i>)	Total Institutional Investor Shareholdings (%)	Total Non-Institutional Investor Shareholdings (%)
Microsoft (<i>US</i>)	73.5	26.5
Apple (<i>US</i>)	61.5	38.6
Amazon (<i>US</i>)	56.1	44.0
Alphabet (<i>US</i>)	79.4	20.6
Facebook (<i>US</i>)	73.0	27.0
Note: Data as of 5 May 2019, to one decimal place. Source: Bloomberg.		

In contrast, China-based digital platforms are characterised by the prevalence of non-institutional shareholding (see Figure 4.4.).

⁷³⁶ See William Lazonick and Mary O’Sullivan, ‘Maximizing shareholder value: a new ideology for corporate governance’ (2000) 29(1) *Economy and Society* 13.

From the above, we consider that the China-based platforms are far less, or not at all, financialised. Their behaviour may thus correspond to the traditional conglomerate

model of the late industrial capitalism that also prevailed in the US before the beginning of the era of financialised capitalism in the late 1970s.

We further explore the varying patterns of ownership by examining the extent of stock ownership by the top five institutional investors in each of the digital platforms that are financialised and, where appropriate, the shareholdings of firm insiders and other non-institutional investors:⁷³⁷

- Microsoft's top five institutional investors own nearly one quarter of total outstanding shares,⁷³⁸ while all insiders combined own less than two per cent, with the majority of insider stock ownership held by Bill Gates.⁷³⁹
- Apple's top five institutional investors own just over one quarter of total outstanding shares,⁷⁴⁰ while all insiders combined own a negligible amount.⁷⁴¹
- Amazon's top five institutional investors own nearly 22 per cent of total outstanding shares,⁷⁴² while all insiders combined own approximately 16 per cent, with the majority of insider stock ownership held by Jeff Bezos.⁷⁴³
- Alphabet's top five institutional investors own nearly one quarter of total outstanding shares,⁷⁴⁴ while all insiders combined own 15 per cent of stock. Insider shareholdings is largely concentrated in ownership by Larry Page, Sergey Brin and Eric Schmidt.⁷⁴⁵
- Facebook's top five institutional investors own just over one quarter of total outstanding shares,⁷⁴⁶ while all insiders combined own approximately 17 per cent, with the majority of insider stock ownership held by Mark Zuckerberg.⁷⁴⁷ Dustin Moskovitz and Eduardo Saverin also own notable shareholdings, yet are neither institutional investors nor insiders.⁷⁴⁸

⁷³⁷ Institutional ownership data sourced from NASDAQ website, based on institutional investors' latest 13F filings. Data on insider and other non-institutional investor ownership taken from firms' Annual Reports (10-K SEC filings).

⁷³⁸ Microsoft's top five institutional shareholders are Vanguard (7.9%), BlackRock (6.6), State Street (4.0), Fidelity (3.3) and Price T Rowe (2.5). Cumulatively, 24.3%.

⁷³⁹ Combined all insiders own 1.4% of Microsoft shares, Bill Gates owns 1.3%.

⁷⁴⁰ Apple's top five institutional shareholders are Vanguard (7.4%), BlackRock (6.4), Berkshire Hathaway (5.4), State Street (4.0) and Fidelity (2.4). Cumulatively, 25.7%.

⁷⁴¹ All insiders aggregated own just 0.1% of Apple shares.

⁷⁴² Amazon's top five institutional shareholders are Vanguard (6.2%), BlackRock (5.2), Fidelity (3.6), Price T Rowe (3.2) and State Street (3.2). Cumulatively, 21.5%.

⁷⁴³ Combined all insiders own 16.1% of Amazon shares, Jeff Bezos owns 16.0%.

⁷⁴⁴ Alphabet's top five institutional shareholders Vanguard (7.3%), BlackRock (6.3), Fidelity (5.3), State Street (3.6) and Price T Rowe (2.4). Cumulatively, 24.9%.

⁷⁴⁵ Larry Page owns 6.7% of Alphabet stock, Sergey Brin owns 6.4% and Eric Schmidt owns 1.4%.

⁷⁴⁶ Facebook's top five institutional shareholders are Vanguard (7.3%), BlackRock (6.2), Fidelity (4.8), Price T Rowe (3.7) and State Street (3.6). Cumulatively, 25.7%.

⁷⁴⁷ Combined all insiders own 17.3% of Facebook shares, Mark Zuckerberg owns 15.7%.

⁷⁴⁸ Dustin Moskovitz owns 1.4% and Eduardo Saverin owns 2.2%.

4.3.1.2.2. Shareholder Voting Rights

In addition to simple measures of stock ownership, to gain insight into the financialisation of digital platforms it is also important to appreciate the nature of voting rights within these firms. Share class differentiation reduces the strength of the link between observed shareholding and voting rights. Unlike Microsoft, Apple and Amazon, which all offer only one class of share, Alphabet and Facebook have differentiated share structures.

Alphabet has three classes of shares: Class A shares, which confer one vote per share; Class B shares, which confer 10 votes per share; and Class C shares, which do not confer any voting rights. Only Class A and Class C are available to purchase on public equity markets, with Class B owned only by insiders and not publicly traded. According to Alphabet's most recent Annual Report, as of 31 December 2018 Larry Page, Sergey Brin, and Eric E. Schmidt beneficially owned approximately 92.8% of outstanding Class B common stock, which represented approximately 56.5% of the voting power of our outstanding common stock. Page, Brin, and Schmidt therefore "have significant influence over management and affairs and over all matters requiring stockholder approval, including the election of directors and significant corporate transactions, such as a merger or other sale of our company or our assets, for the foreseeable future."⁷⁴⁹

Similarly, Facebook has a dual-class share structure: Class A shares conferring one vote per share and Class B shares conferring 10 votes per share. Class A can be publicly traded, while Class B is reserved for insiders. Due to his ownership of Class B shares, Mark Zuckerberg, Facebook's founder, chairman and chief executive officer, has control over key decision making. According to Facebook's latest Annual Report:

Mark Zuckerberg...is able to exercise voting rights with respect to a majority of the voting power of our outstanding capital stock and therefore has the ability to control the outcome of matters submitted to our stockholders for approval, including the election of directors and any merger, consolidation, or sale of all or substantially all of our assets.⁷⁵⁰

Based on the above observations regarding shareholding and voting power, we may expect Amazon, Facebook and Alphabet to be relatively less financialised in comparison to Apple and Microsoft. In the case of Amazon, while voting power is not entrenched through share class differentiation, Jeff Bezos remains the largest shareholder and therefore has greatest voting power. Mark Zuckerberg not only owns the most Facebook stock, but due to Facebook's dual-class structure, he has disproportionately great voting power. Likewise, Alphabet's three primary insiders – Larry Page, Sergey Brin, and Eric Schmidt – own sizeable proportions of stock and have outsized voting power due to Alphabet's differentiated share classes. In contrast, insiders of Microsoft and Apple benefit from neither meaningful proportions of share ownership nor voting power con

749 Alphabet Q4 2018 10-K SEC Filing.

750 Facebook Q4 2018 10-K SEC Filing.

ferred by share class differentiation. This likely gives greater influence to the institutional investor shareholders of these two platforms.

4.3.1.2.3. Dividends, Share Buybacks and Investment

As noted, a primary indicator of a firm's financialisation is the amount of cash they dedicate to increasing the welfare of their shareholders through issuing dividends or inflating stock prices through share repurchases, potentially at the expense of other goals such as R&D investment. Here we examine the sums the largest five digital platforms spent on issuing dividends, repurchasing their own shares and R&D over five years from 2014 to 2018:⁷⁵¹

- Microsoft returned cash to its shareholders in every quarter, spending an average of \$10.7 billion per year on dividends and \$11.1 billion per year on share repurchases. At the same time, Microsoft spent an average of \$12.2 billion per year on R&D. Expenditure on dividends and share buybacks combined as a percentage of net income increased markedly across the period, from 71% to 130%. Expenditure on R&D as a proportion of net income also increased, from 52% to 74% (see Figure 4.6.).

Figure 4.6. Microsoft: Buybacks, Dividends and R&D

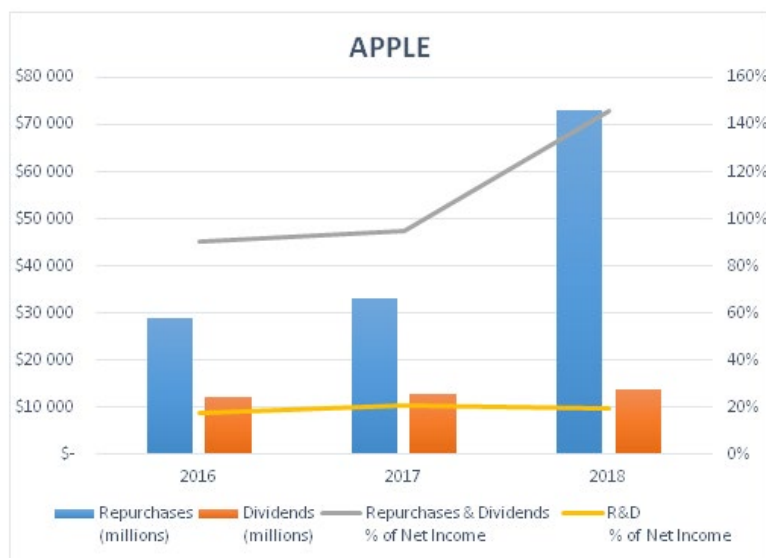

Source: Authors' compilation

- Apple returned cash to its shareholders in every quarter, spending an average of \$43.1 billion per year on dividends and \$12.2 billion per year on share repurchases. At the same time, Apple spent an average of \$8.0 billion per year on R&D. Expenditure on dividends and share buybacks combined as a percentage

⁷⁵¹ Net Income, Dividend and Share Repurchase data sourced from the digital platforms' Annual Reports (10-K SEC filings) and Quarterly Earnings Reports. R&D data sourced from the R&D data from Strategy&, 'The 2018 Global Innovation 1000 study' (PwC 2018).

of net income increased slightly across the period, from 142% to 146%. Expenditure on R&D as a proportion of net income also increased, from 11% to 19%. (see Figure 4.7.)

Figure 4.7.: Apple: Buybacks, Dividends and R&D

Source: Authors' compilation

- Amazon returned no cash to its shareholders across the period. At the same time, Amazon spent an average of \$13.4 billion per year on R&D. Expenditure on R&D as a percentage of net income increased markedly across the period, from -2726% in 2014, when net income was negative, to 225% in 2018 (see Figure 4.8.).

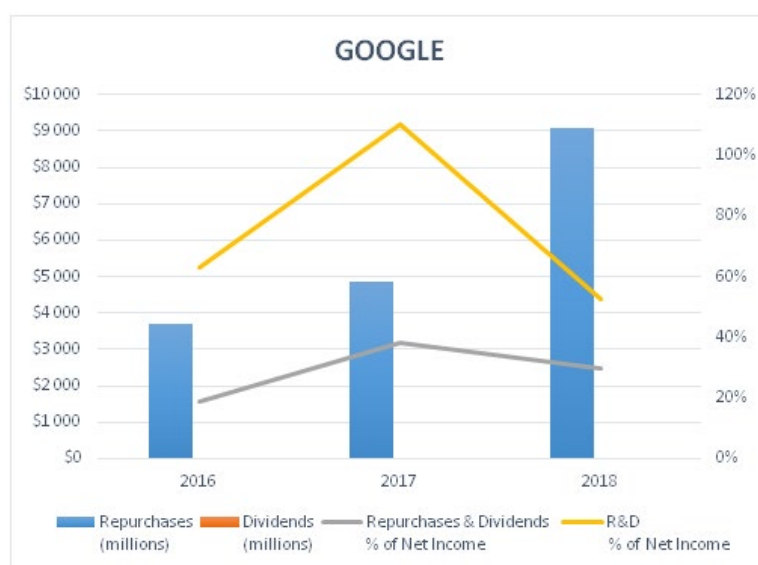

Figure 4.8. Amazon: Buybacks, Dividends and R&D

Source: Author's compilation

- Alphabet began to return cash to shareholders through dividends in the last quarter of 2015. It issued further dividends two quarters of 2016, three quarters of 2017 and every quarter of 2018. Across the period, Alphabet spent an average of \$3.9 billion per year on dividends. Alphabet engaged in no share repurchasing activity. In contrast, R&D expenditure was recorded across the entire period, averaging \$11.9 billion per year. Expenditure on dividends as a percentage of net income increased from 0% in 2014 to 11% in 2015 when dividend payments began and 30% by 2018. Expenditure on R&D as a proportion of net income increased slightly from 51% in 2014 to 53% in 2018 (see Figure 4.9.).

Figure 4.9. Alphabet (Google): Buybacks, Dividends and R&D

Source: Author's compilation

- Facebook began to return cash to shareholders through dividends in the first quarter of 2017. It issued dividends throughout 2017 and 2018. Across the period, Facebook spent an average of \$3.0 billion per year on dividends. Facebook engaged in no share repurchasing activity. In contrast, R&D expenditure was recorded across the entire period, averaging \$4.5 billion per year. Expenditure on dividends as a percentage of net income increased from 0% in 2014 to 12% in 2017 when dividend payments began and 58% by 2018. Expenditure on R&D as a proportion of net income decreased from 48% in 2014 to 35% in 2018 (see Figure 4.10.).

Figure 4.10. Facebook: Buybacks, Dividends and R&D

Source: Author's compilation

Our contention that Microsoft and Apple are characterised by a greater degree of financialisation, due to the nature of their share ownership and voting rights, appears to be supported by the data on dividends, share buybacks and R&D expenditure. From this perspective, Amazon, Alphabet and Facebook could more readily be likened to pre-financialisation era conglomerates. We note, however, that the strong merger activity undertaken by Microsoft and Facebook undermines the traditional distinction between 'downsize and distribute' and 'retain and reinvest'. The term 'expand and distribute' may be more apt, describing a hybrid period of financialisation and digitalisation.

4.3.1.3. Futurity and the financial dimension of competition in the digital economy

Financial markets play a crucial role in determining the market value of corporations, and consequently the compensation of their management. Due to futurity, market valuation relies on the expectation of future profits, rather than on actual profits being made by the firm. This may explain a number of competitive strategies that would often not make sense if one only takes into account product competition. This dimension of competition may have significant effects on productivity, innovation and the share of surplus value between the different segments of digital value chains.

Digital platform's growing output is not motivated by their increasing profitability in product markets, as it has by now been well documented that many of these platforms have been incurring important losses or not making profits for a considerable period of time. Motivated by network effects and the quest for the holy grail of the 'tipping point' that will enable them to become the winners in the 'winner takes most' competition, digital platforms drive to increase its market value is motivated by the signal this provides to financial markets. Indeed, their strategy is to increase their market share, even in the presence of negative profit margins. In this they are driven by the futurity of financialised capitalism, which value not their current cash flow but expected profits in the short and medium term.

One way to understand the importance of financialisation in this industry as the main drive of value creation is to see how much of these companies' current market worth is expected to be realised soon and how much relies on expected returns into the future. In February 2017, The Economist identified the ten most important digital platforms and three promising ones and distinguished their market value into three parts: value which has already been realised in the form of net cash held, the present value of expected earnings in the next four years, and the value attributable to what happens after 2020⁷⁵² (see Chart 4.1.).

Chart 4.1.: Market value of technology firms and futurity

Source: Economist (February 23, 2017)

The article notes how the shares of technology firms trade on their highest ratio to sales, four of the world's most valuable firms being tech companies: Apple, Alphabet, Microsoft and Amazon. While over 40% of Samsung's and Apple's value can be explained by cash and near-term profits, as the firms do not follow a rapid growth strategy and are low-risk, for some of the 'raciest firms', such as Tesla, 90% of their value concerns expected profits to be made after 2020. As it is explained in the article, Amazon is 'one of the most optimistically valued firms', as 92% of its current worth refers to profits after 2020. Only a third of the \$1 trillion of Apple's value is justified by its profitable cloud-computing arm, AWS, while the rest of the activities of the firm in e-commerce, television and films, as well as logistics, 'barely makes money despite generating large sales'⁷⁵³. Nor is it growing particularly fast for its industry. To justify this valuation one needs to believe that the company has become a sort of 'giant utility for e-commerce which by 2025 cranks out

⁷⁵² See, <https://www.economist.com/business/2017/02/23/are-technology-firms-madly-overvalued>.

⁷⁵³ Ibid.

huge profits, more than any other firm in America'. Some of the other firms in the list, such as Alibaba, Tencent, Facebook and Alphabet, see their sales growing at an annual rate of over 20%, with high margins. A number of 'blue-sky' firms, such as Uber and Snap are unprofitable but witness explosive sales growth.

Hedge fund managers are not anticipating the same profit stream twice for each functionality. For example, Facebook is not expected to become a force in search, while Google is not expected to conquer social media. Hence, the reason that these firms are highly valued is their monopolistic potential as they control important bottlenecks in the attention and prediction economy.

Digital platforms have reached almost incredible market valuations (see Figure 4.11)

Figure 4.11. Market Capitalisation of the top 10 Digital Platforms

Source: Author's compilation

Notes and Source: Market capitalisation in billions (USD), as at 5/5/19. Source: Bloomberg Markets

List of platforms based on P Evans and A Gawer, 'The Rise of the Platform Enterprise: A Global Survey' (2016).

Rankings updated for market capitalisation as at 5/5/19, including newly floated companies

The role of financial markets in the valuation of these digital platforms is also manifested by the important role played by institutional investors and certain star venture capitalists that invest in technology firms, start-ups and Big Tech, accompanying them along the process, or for part of it, and playing a very important role of quality certification that impacts significantly on the market valuation of these companies, and may make them or break them.

4.3.2. Competitive advantage beyond horizontal competition

Competitive strategy analysis focuses on competition, taking into account the corporate strategy to maximise the firm's performance, in terms of surplus value and economic profit⁷⁵⁴. Corporations seek a competitive advantage, either by imitating successful competitors while lowering their costs, or by differentiating themselves from their competitors, by developing internal resources and capabilities and designing strategies to exploit these differences. The business environment in which competitive advantage strategies are integrated is formed by the relationship the corporation has with three sets of players: customers, suppliers, and competitors⁷⁵⁵. Firms make profits but they must also provide value to their customers. 'Value is created when the price the customer is willing to pay for a product exceeds the costs incurred by the firm'⁷⁵⁶. This surplus is distributed between the customers and the producers by the forces of competition. If competition is strong, consumers will receive the higher percentage of the surplus value (the so called consumer surplus, which measures the difference between the price they paid and the price they were willing to pay). The rest of the surplus value will be received by producers (the so called producer surplus, which measures the difference between the amount a producer receives and the minimum amount the producer is willing to accept for the product). The profitability of industries varies, some earning high rates of profit, while others can cover a little more than their cost of capital⁷⁵⁷. This largely depends on the degree of competition that prevails in each industry, as intense price competition generally leads to weak margins. Profitability within a specific industry may also be quite different, some firms earning significant profits, while others struggling to maintain themselves on the market⁷⁵⁸.

The most widely used competition framework in business strategy is that put forward by Michael Porter, the 'five forces of competition framework'⁷⁵⁹.

754 Economic profit is 'the surplus available after all inputs (including capital) have been paid for': R M Grant, *Contemporary Strategy Analysis* (Wiley, 2013) 38. To the extent that financial markets look to the actual but also expected stream of economic profit (or cash flows), the Net Present Value (NPV) (or stock market value) of a firm provides a forward-looking performance measure, which has become extremely important, in view of the financialisation of the economy and the intense competition between capitals. Enterprise value depends on three drivers: rate of return on capital, cost of capital and profit growth: *Ibid.*, 42.

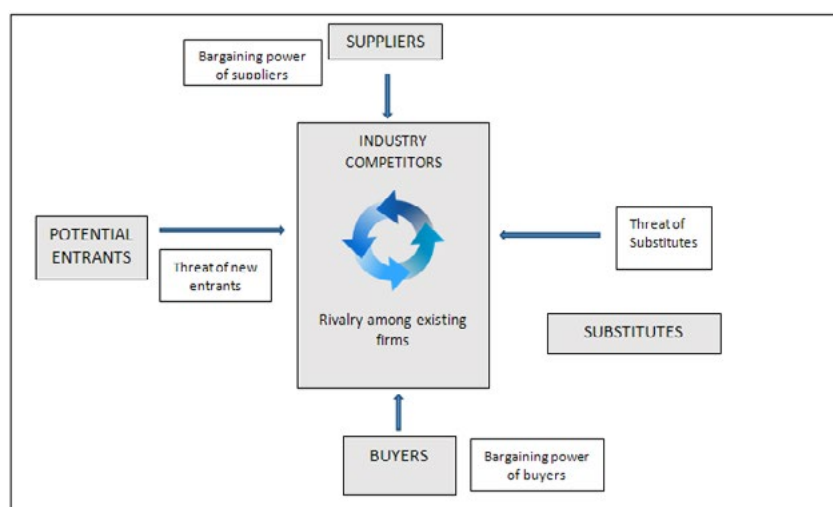

755 *Ibid.*, 61.

756 *Ibid.*, 62.

757 *Ibid.*

758 The advent of the digital economy has led to the development of what has been characterized as the rise of "superstar firms" which are able to take advantage of technology, including Big Data and artificial intelligence, in understanding better than "standard" firms the competitive game. See, D. Autor, D. Dorn, L.F. Katz, Ch. Patterson, J. Van Reenen, *The Fall of the Labor Share and the Rise of Superstar Firms*, NBER Working Paper No. 23396 (May 2017).

759 M. E. Porter, *The Five Competitive Forces that Shape Strategy*, (January 2008) *Harvard Business Review* 25.

Figure.4.12: Porter's five forces

Source: R M Grant, *Contemporary Strategy Analysis* (Wiley, 2013) 65.

According to this framework, the profitability of an industry is determined by five sources of competitive pressure: competition from substitutes, competition from new entrants in the industry, competition from established rivals, which can be characterised as sources of 'horizontal' competition, and competition from the bargaining power of suppliers and the power of buyers, which can be characterised as sources of 'vertical competition'.

In the context of the 'winner takes most' competition of the digital economy and the role of financial markets valuation in competitive strategy in the era of financialisation, vertical competition becomes an important dimension of the competitive game.

Competition economics has largely focused on horizontal competition from established competitors (producing substitute products), or on the threat of entry of potential competitors. Rivalry between established competitors is often measured by reference to the level of market concentration, often measured by a concentration ratio, the market share of the largest producers in a specific market. However, it is still unclear how the level of market concentration impacts on profitability, and consequently the allocation of the surplus between consumers and producers⁷⁶⁰. The likelihood of a new entry (potential competition) largely depends on barriers to entry, that is, an advantage that an established firm enjoys vis-à-vis its rivals, which may include economies of scale (to the

760 See, the different positions of the so called 'Harvard' or Structure-Conduct-Performance school, which found a causal link between a concentrated market structure and profitability [see, J.S. Bain, *Relation of Profit Rate to Industry Concentration: American Manufacturing, 1936–1940*, (1951) 65 *Quarterly Journal of Economics* 293 (who showed that showed that the after-tax returns on shareholder equity across forty-two U.S. manufacturing industries were higher when the eight-firm concentration ratio (sum of the shares of the eight leading firms) was above 70 percent); H.M. Mann, *Seller Concentration, Barriers to Entry and Rates of Return in Thirty Industries*, (1966) 48 *Rev Econ & Statistics* 296], and that of the so called 'Chicago' school, which found that this effect was weak statistically and usually quite small [see, Y. Brozen, *Bain's Concentration and Rates of Returns, Revisited*, (1971) 14 *Journal of Law & Economics* 351; H. Demsetz, *Two Systems of Belief about Monopoly*, in H. J. Goldschmidt & H. M. Mann, (eds), *Industrial Concentration: The New Learning* (Little, Brown, 1974) 164].

extent that large, indivisible investments in production facilities, research & technology or marketing may be more easily amortized over a large volume of output), absolute cost advantages (which may come from an easy access to an indispensable input), capital requirements (because of the large fixed costs required in order to kick start economic activity in an industry), product differentiation (as it might be quite difficult to enter a market where consumers have strong loyalty ties to existing brands), access to channels of efficient distribution, strategic barriers to entry because of competitive strategies that aim to increase the potential rivals' costs if they enter the market, legal and regulatory barriers etc. Competition law aims to limit the effectiveness of barriers to entry, so as to increase the 'contestability' of the market⁷⁶¹.

In contrast, vertical competition has not been the focus of competition economics, even if it may play a significant role with regard to the allocation of the total surplus value that is generated by a value chain. The relative bargaining power of a supplier upstream, or of a customer downstream, have been considered as playing a less important role than 'horizontal competition', in particular because it is assumed that, in most cases, they play a quite limited role on the overall economic efficiency of the transactions. To the extent that economic efficiency still constitutes one of the main goals of competition law, rather than fairness in the distribution of the total surplus value, the exercise of relative bargaining power is not considered as being a primary concern for competition law, with the exception of course of the situation where its exercise may harm economic efficiency (e.g. the rather confined case of monopsony or buyer power). Vertical competition may however become an important concern, if one wants to focus on productivity and on the ability of 'superstar' large digital platforms to pull away from competition and enjoy tremendous levels of profitability, without these accumulated profits being used for productive investments.

In the digital economy, what constitutes an established or a potential competitor becomes also blurred, as the companies are actively pursuing strategies to alter industry structure in order to alleviate competitive pressures, by positioning the company where competition, horizontal and vertical, is the weakest⁷⁶². In the digital economy, important network effects lead to 'winner- takes- most' competition, with only one platform controlling a market, or being the significant player on a relevant market (thus restricting horizontal competition), or more broadly dominating a value chain (thus restricting vertical competition). Markets characterised by platform competition are thus horizontally concentrated, sometimes to such an extent that the second or third player in the market may not offer a viable competitive alternative to the established platform. Inter-platform competition remains weak, and there is significant *inequality in the distribution of market shares* among horizontal competitors.

At the same time, the centralized platform forms a bottleneck, with the power to determine the allocation of the surplus generated by the value chain between the various

761 W.J. Baumol, J.C. Panzar & R.D. Willig, *Contestable Markets and the Theory of Industry Structure* (Harcourt Brace Jovanovic, 1982).

762 R.M. Grant, *Contemporary Strategy Analysis* (Wiley, 2013) 74-76.

contributors, and in particular to keep the overwhelming part of this surplus, thus accumulating significant profits (exercising vertical economic power). In view of the anchoring of users and the low levels of switching to competing platforms, the platform operators can be confident that the reduction of vertical competition, between the different segments of the value chain, with regard to the allocation of the total surplus value generated by the value chain, will not lead to the desertion of their platform from a significant number of applications developers. Hence, value chains dominated by digital platforms are also marked by a very *unequal distribution of profits* between the established platforms and the participants to their ecosystem.

The digital economy gives rise to a variety of strategies to acquire competitive advantage and convert this to surplus value to be later collected in product and financial markets. In this fast-moving environment, innovation competition provides the main constraint to 'winner-takes-most' competition, as new economic actors rely on cost-cutting technology to break into markets, disrupt the existing competitive structure, and eventually acquire a position of economic power, before they give way to new actors making a more efficient use of the technology or relying on a better technological alternative.

4.3.3. Vertical competition: introducing the concept

Although we have a number of theories explaining horizontal competition, with some exceptions, vertical competition has been largely ignored in competition law and economics literature.

The issue was first raised in competition law literature on vertical restraints, in particular dealing with contexts in which the supplier and distributors may be in competition with each other (e.g. dual distribution, private labels). Robert Steiner has advanced the view that there are two forms of competition that co-exist in vertical structures: First, the horizontal competition between the different vertical structures or between the retailers of the same vertical structure, and second, the vertical competition between the different levels of the vertical structure, such as suppliers versus retailers over the sharing of the profits of the vertical chain⁷⁶³. Steiner perceives competition as a struggle between firms aiming to capture a perceptible share of markets from each other (which is the traditional view of horizontal competition) but also an important share of sales or margins. It follows that suppliers and retailers engage 'in a form of vertical intrabrand competition by attempting to increase their vertical market share (VMS) at each other's expense', where vertical market share consists in their respective shares of a brand's retail price⁷⁶⁴. In contrast to the Chicago school and Transaction Cost Economics (TCE) approaches to vertical restraints, this literature perceives the relation between the different levels of the vertical chain as not being exclusively complementary, but also as antagonistic⁷⁶⁵.

763 R.L. Steiner, 'Intrabrand Competition-Stepchild of Antitrust', (1991) 36 The Antitrust Bulletin 155, 161.

764 Ibid.

765 R.L. Steiner, 'The Inverse Association Between the Margins of Manufacturers and Retailers' (1993) 8 Review of Industrial Organization 717; R.L. Steiner, 'The Virtual Equivalence of Horizontal and Vertical Competition—An Analysis of the Sources of Market Power in Consumer Goods Industries' (2007 Loyola Antitrust Colloquium) 7 <http://www.luc.edu/law/>

Steiner suggested an alternative approach for vertical restraints that affect intrabrand competition between retailers. He considered that the 'single-stage paradigm' of vertical restraints, which emphasizes the analysis of the existence of interbrand competition and largely ignores the role of vertical competition, does not correspond to commercial reality. The dual stage model, he suggested, will not only focus on the existence of market power at each level and/or horizontal competition between suppliers or between dealers, but will also examine competitive relationships between manufacturers and retailers⁷⁶⁶. Consequently, the 'locus of market power' and consequently the source of the restraint, supplier or retailer market power, should be an important consideration in the enforcement of competition law⁷⁶⁷.

One may focus on competition in products market and explore the process of value generation in the context of a typical input-output process. In the digital economy, the main input is data, hence we will frame our analysis accordingly. Any economic process of production relies on the use of labour, technology, and some form of social organization of the production process that transform some inputs to outputs, most often commercialised on a market. The various labour processes that form the production process rely on inputs (raw materials or machines, labour), some of them 'used up in the course of a production cycle' (materials), and others that may be used in a more long-lasting way, in different production cycles, although they are also subject to a certain amount of depreciation because of their use (capital)⁷⁶⁸. When the production process leads to output that is 'in excess of what is needed for reproducing and replenishing the labo(u)r, tools materials, and other inputs used or used up in production', so that the next production cycle can begin under the same conditions, this is considered as a 'surplus product', as this output is available for investment in the level of production, or for capitalist consumption⁷⁶⁹.

Hence, 'surplus product' is the part of the total output that does not constitute the "necessary product" to maintain the previous level of consumption. The 'necessary product' includes the output used for the replacement of capital goods and materials used in the production process, the output used for the maintenance and replacement of the capital goods used in production and the output used so as to guarantee the consumption of producers at their customary standard of living.

The total surplus may be invested in 'labour-saving technology' or technical change, which enables a greater production of output with a given amount of labour, or in 'capital-goods saving technical change', which 'reduces the amount of capital goods or the

768 See the analysis in I. Lianos, *The Vertical Horizontal Dichotomy in Competition Law: Some Reflections with Regard to Dual Distribution and Private Labels*, A. Ezrachi & U. Bernitz, (eds.), *Private Labels, Brands and Competition Policy* (OUP, 2009), 161.

769 Ibid., p. 67.

quantity of materials required to produce the total product⁷⁷⁰. The total output may also be enlarged because of an increase in the 'Intensity of labour', the producers keeping their amount of work constant, although they work harder⁷⁷¹.

How does this process of production take place in the context of the digital economy? As previously explained, data is the raw material of the digital economy. Digital platforms dominate 'Big-data driven' systems, to the extent that they constitute 'scalable data systems', data being connected through the web or other IT platforms, and the operation of various apps where information and experiences are exchanged in real time.⁷⁷² As with any other production process, which relies on inputs, including commodities, in order to produce outputs, data may be considered as the basic input in the input-output process of the digital economy. These production processes generate a surplus product, the latter being provided a value, either by a process of trade and exchange on product markets (value generated by its current use), and/or, as we will examine in more detail, on financial markets (value generated by expectations about its future use).

Lets' focus for simplicity on value generated by current use. Drawing the input-output production process for the digital economy is rather complex, as there is a great variety of digital platforms active in various fields of economic activity. What we will present is a simplified form that would, hopefully, describe the basic process of transformation of inputs into outputs occurring in the digital economy. A data-driven input-output process may be described as englobing the following steps⁷⁷³:

- *Data generation or data capture*: In this segment a huge amount of data, about consumer transactions, bio-physical phenomena and conditions, such as the weather, soil consistency, health status, are generated and ultimately captured by a variety of sources: sensors, interacting devices, Mobile apps, social media and networks, posts, blogs, eMails, scientific publications, texts, antennas, videos and other connecting sources through several different devices (e.g. smartphones, Internet of Things, the cloud, PCs etc). Consumers are attracted to these various sources of data capture by being offered products and services "for free".
- *Data storage or data-warehousing*: this data is stored quickly in elaborate storage systems (e.g. the Cloud), which ensure that the data will be maintained, being relatively easy to access, secure and amenable to verification.
- *Data processing*, which connects heterogeneous data (e.g. pictures, text, video) also establishing protocols to confirm data veracity. Various methods are applied at this level of data analysis: (i) statistical methods of correlation among big data, reduction algorithms enabling the sampling of data and other tech-

773 Ibid.

niques aiming to minimize the loss of data, (ii) data mining that aims to infer patterns from data (including clustering and regression analysis), (iii) artificial neural networks which are used for pattern recognition and image analysis, (iv) social network analysis enabling the study of social relations, social systems and networks.

- *Data sharing and communication*: this step aims to visualize and communicate or share data with the stakeholders. Various visualization tools may enable the stakeholders to interpret the data in order to establish robust causal connections, that is causal dependencies in the real world that may also lead to accurate predictions of the phenomena on which data have been collected (e.g. consumer needs and eventually future purchasing decisions of consumers, future yields on the basis of the quality of soil, weather conditions and the composition of fertilizers).
- *Data commercialization and monetization*: the process of assembling value through the creation of datasets merging different types of data (structured and unstructured), for instance integrating location data with customer data or public data with private data and of converting the intangible value of data into real value. Quite often this monetization occurs by selling this data to a group of consumers with indirect network externalities to the group of consumers whose data has been the input of the value chain, that is the first group of consumers is more willing to 'be on board' if they expect the other group of consumers to be equally popular. Data monetization requires "high technical data capabilities" (e.g. network capacities enabling the collection, storage and retrieval of data) and "high analytical capabilities" (the analytical skills needed to exploit the data). Of course there are different possibilities for monetization and various business models. Data may become an important asset for the company to protect, and merely used in its internal production process, or a valuable asset to exchange in data markets.

It is noteworthy that contrary to traditional commodity / value chains, where the final consumer sits at the end-point of the supply chain, the chain describing the entire input-output process bringing a product or service from initial conception to the consumer's hands, in data-driven markets, where unstructured data constitutes the raw material, the consumer most often (but not always, as data may not be personal data) constitutes the first input, and therefore the first segment in the value chain at the end of which sit the generators of capital, institutional investors, venture capitalists, investment banks and others that profit from the monetization of data. This inversion of the role of the consumer in the input-output process for data-driven value chains results from digitalisation, which makes possible the capture, storage, processing and analysis of data at a scale never achieved before.

In addition to competing with firms in the same relevant market and/or potential horizontal competitors at each level of the value chain, there is also vertical competition

among the firms forming part of the same value chain as to which one will be able to capture the largest share of the surplus value generated by the value chain. Depending on the governance of these value chains (see Chapter 3) some firms may be able to raise their markup prices above average costs, which will affect the part of the surplus generated by the other segments of the value chain. Referring to the competition theory of Michael Kalecki, who modeled the mark up as being a function of ‘the degree of monopoly of the firm position’⁷⁷⁴, William Milberg and Deborah Winkler note that ‘the degree of monopoly is determined by a set of environmental or institutional factors, including industrial concentration, advertising expenditure levels, the influence of labor unions [countervailing powers], and changes in the ration of fixed to variable costs’⁷⁷⁵. Firms determine their output price by marking up over average prime costs, while taking into account the output-weighted average price charged by their competitors in the industry, taking into account their degree of monopoly in the industry⁷⁷⁶. According to the same authors, a large deviation between the firm’s price and the average industry’s price shows that there is less competition among firms in the industry, this being usually associated with a high markup. Firms aim of course to limit their prime costs so as to be able to increase their mark up, if other firms in the industry do not benefit from these lower prime costs⁷⁷⁷. According to this conception, contrary to neoclassical price theory, prices are not understood as ‘signals’ of productive efficiency or inefficiency and ‘pricing decisions do not serve the role of bringing allocative efficiency’ but are rather driven by the firm’s ‘long-term objectives for investment and growth’⁷⁷⁸.

A firm may increase its mark up by three strategies: (i) raise the product price, (ii) lower input prices, and (iii) raise productivity⁷⁷⁹. The first strategy may be adopted in case the firm faces weakened horizontal competition, to the extent that the reduction of output cannot be easily substituted by actual or potential competitors present in the same market. An additional condition for the success of this strategy is that the firm faces weakened vertical competition, for instance by being able to exercise selling power downstream, without this strategy being compromised by the existence of a countervailing power downstream. This weakened vertical competition supposes the existence of vertical market power, which as we will explain may have multiple sources. The second strategy again supposes the existence of vertical power, this time upstream, as the firm should be able to exercise buyer or superior bargaining power vis-à-vis its suppliers of inputs. The third strategy involves the ability of the firm to invest in superior resources and to develop superior capabilities that would enable it to sustain its competitive advantage.

779 Ibid.

Transposing the discussion in the context of the data economy, digital platforms may theoretically increase their mark ups by raising their product price in one of the markets on which they are present (price mark up), to the extent that this is the 'money side' of the platform. There is also the subsidised side, on which often the digital platforms offer their products and services for 'free'⁷⁸⁰, although one may also conceive that mark ups could take the form of the harvesting of more personal data, and therefore represent the consequent reduction in privacy, considered in this context as a parameter of quality (a data mark up). Digital platforms may take advantage of their vertical power to lower their input prices. This, for instance, may take the form of suppressing the wages of their employees or dependent self-employed, or by taking advantage of heightened competition among suppliers and the existence of excess capacity upstream. They often achieve this by a strategy of lowering the barriers of entry in upstream markets and therefore provoking the continuous entry by new firms into the production of goods and services that serve as inputs to the outputs of the digital platform, for instance through the reduction of costs for app developers to participate to their app store⁷⁸¹. This increased competition between their suppliers increases their mark ups. Digital platforms may also rely on their large installed base of users for providing inputs for free, through for instance the collection of large scale data on queries that can be used to train the algorithms of a search engine managed by the platform, or for instance through freely provided content for media platforms (e.g. blogs for a news' aggregator, videos for a video-sharing website), which are then monetised in different ways.

Hence, in the digital economy context one needs to take a more dynamic perspective than product market competition. The strategy of the various firms in the digital economy is to capture a disproportionate amount of the surplus value created by innovation resulting from the emergence of the new industry resulting from the new technological developments. In some situations, the most effective strategy will be to opt for an 'open architecture' that nurtures complementarity through an open eco- system, should a system of 'open innovation' be the most effective way to generate higher value in this industry⁷⁸². In other situations, firms may opt for a 'walled garden approach', opting for a closed architecture with regard to firms with competing assets and capabilities entering the value chain while keeping it open for firms with complementary assets. Finally, in other circumstances, firms may opt for vertical integration; taking full control over the rents generated by the complementarities brought by the innovation, whilst maintaining the possibility to exclude or marginalize any new entrant, for instance, by denying interoperability with regard to some indispensable technological interfaces. As the focus of competition authorities switches to innovation competition, it becomes important to ensure that the players contributing to this effort are properly incentivized with regard

780 For a discussion of zero or negatively priced markets, see J.M. Newman, *Antitrust in zero-priced markets: foundations*, (2015) 164 *University of Pennsylvania Law Review* 149.

781 The emergence of the app economy has been a significant feature of recent years. The market for apps is growing, and it is estimated that between iOS, Android, and smaller platforms, apps could generate \$101 billion annually by 2020:

782 See, for instance, the discussion in A. Gawer, 'Bridging Differing Perspectives on Technological Platforms: Toward an Integrative Framework' (2014) 43 *Research Policy* 1239.

to their returns on their investment on innovation, in particular if this takes place in an open innovation ecosystem⁷⁸³.

It is also important to keep in mind the role of *vertical innovation competition* in challenging competitive bottlenecks resulting from the control of essential inputs by dominant players in an industry. In a digital economy marked by network effects, it is quite frequent that the position of incumbents can only be challenged by firms vertically situated in complementary markets that may also benefit from network effects, rather than competitors situated on the same relevant market. For instance, the dominant position of IBM on the computer industry until the early 1980s was not challenged by another hardware company, but by Microsoft, which was present in the complementary segment of software, and controlled the market of the operating system, an essential input for personal computers (PCs). Microsoft, with time, benefitted from important network effects, which provided it with the power to commodify hardware and thus change the computer industry architecture, thus becoming able to acquire the largest percentage of the surplus value generated by the industry, the centre of power moving from hardware to software in the mid- 1980s– 90s⁷⁸⁴.

Business studies research by Jacobides and MacDuffie has compared the process of disintegration and value migration in the computer industry, where in the process of twenty years between 1980s and 2000s the industry was transformed from single brand value chains to heterogeneous value chains, in comparison wto the relative stability of the relation between Original Equipment Manufacturers (OEMs) and complementors in the automotive industry during the same period, as both sectors witnessed a process of vertical des-integration (see Figure 4.13. for the computer industry)⁷⁸⁵.

Figure 4.13.: The des-integration of the computer industry

785 M.G. Jacobides & J. P. MacDuffie, How to Drive Value Your Way, (2013) July-August Harvard Business Review 92.

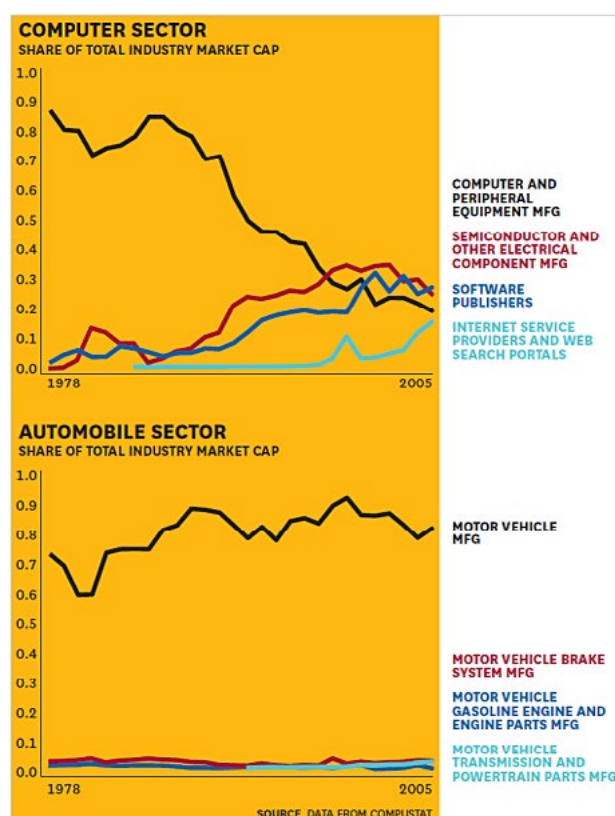

Jacobides and MacDuffie show that 'industry disaggregation' was not inevitable and that '(m)any industries characterized by intense competition and innovation – including those that are vulnerable to highly disruptive technologies – are likely to remain tightly integrated and dominated by traditional players'⁷⁸⁶. They provided the example of the automotive industry. Indeed, OEMs in the automotive industry managed to keep a constant share of their industry's total market capitalization, even if they had massively recourse to outsourcing and despite intense horizontal competition between carmakers⁷⁸⁷. The value has not 'migrated upstream (or downstream to aftermarket products and services)' but stayed with the OEMs (see Figure 4.14.)⁷⁸⁸. In contrast, in the computer industry value has shifted upstream (e.g. Intel) and downstream (e.g. Microsoft), as these companies managed to control the customer experience (see Figure 4.15.).

Source: M.G. Jacobides & J. P. MacDuffie, *How to Drive Value Your Way*, (2013) July-August *Harvard Business Review* 92, 96.

Jacobides and MacDuffie explain that 'Microsoft and Intel ("Intel Inside") succeeded not only in asserting their brands over the OEMs but in convincing consumers that they were in the driving force behind the entire computing experience'⁷⁸⁹. Furthermore, they note that the vertical des-integration in the automotive industry was based on hierarchical non-modular structures and proprietary (closed) standards (e.g. each brand's own, non-compatible navigation system); OEMs in the automotive industry also kept control of most critical and differentiating assets; they were responsible for achieving end-product differentiation, supported by the brand; they had near-exclusive control over distribution through the franchised dealer model and had the responsibility for regulatory compliance and being accountable for product defects/failures (guarantor of quality)⁷⁹⁰. In contrast, computer OEMs outsourced component design and production responsibilities to suppliers, this outsourcing leading to vertical unbundling with the creation of a set of modular, open-access components⁷⁹¹. The vertical unbundling undermined the OEM's system integrator role as suppliers could standardize components across OEMs⁷⁹². The result is that the 'locus of differentiability' moved to suppliers who

789 Ibid., 96

790 Ibid.

791 Ibid.

792 Ibid.

became the guarantors of quality for their respective component⁷⁹³. Suppliers became 'bottlenecks' by taking up positions that give them control over scarce resources, allowing them to capture a bigger share of value⁷⁹⁴. The OEMs could not revert the trend as they lost the expertise within their firm's boundaries, also due to the industry's short product cycles (measured in months)⁷⁹⁵.

To the extent that, in view of its essential characteristic of futurity, the main source of value in the digital economy comes from valuation by financial markets, one may also identify the importance of attracting capital as a dimension of competition.

This dimension is often ignored by research putting forward the view that the competition game is transformed by the emergence of intensive oligopolistic competition as the various large digital platforms (Big Tech) move outside their core business activity in adjacent or overlapping fields of activity on which they become strong rivals (see Table 4.1.)⁷⁹⁶.

Petit, *Technology Giants, the Moligopoly Hypothesis and Holistic Competition: A Primer* (October 20, 2016). Available at SSRN: <https://ssrn.com/abstract=2856502> or <http://dx.doi.org/10.2139/ssrn.2856502> (who includes a comparable table showing the overlaps between the various digital platforms).

797 AMZN: Amazon, AAPL: Apple, GOOG: Alphabet (Google), FB: Facebook, MSFT: Microsoft.

The argument is that it is indifferent if digital platforms dominate specific relevant markets, as in reality they compete with each other, by offering a mix of products and services, and thus forming competing conglomerates. While recognizing the superior position held by each digital platform on its core business activity they are subject to a variety of competitive pressures exerted across industries by other technology or non-technology firms. The top 3 competitors that each of these Big Tech companies recognize as their rivals in their financial reports and other financial databases are the other Big Tech, even if these are not present in their core market⁷⁹⁸. The argument goes that the dynamic nature of competition and disruptive innovation in technology markets, and the risk of negative feedback loops that would generate a 'death spiral' and may rapidly erase any dominance these firms were able to acquire, generates uncertainty that pushes these digital platforms to expand their output (in their core business activity as well as in adjacent markets) and behave as competing oligopolies, hoping to 'maintain the ability to "hop" to the next (disruptive) "dominant design"'⁷⁹⁹. Competition takes place in various dimensions, beyond product and service markets, in particular entrepreneurial assets but more significantly 'non consumption'⁸⁰⁰.

Petit coins the term 'moligopoly' merging the terms 'monopoly' and 'oligopoly' to illustrate the nature of the competitive game, which is that the (moligopoly) firm 'engages into competition against the non-consumption in search of new and low end market footholds.'⁸⁰¹ Like the story of Don Quixote tilting at windmills, which he takes for giants, this battle for competitive survival looks like it will end in the same way, Don Quixote knocked of his horse... This type of head to head, disruptive competition, however, almost never concerns the core markets where the technology firms holds its dominant position. But the lack of competition in these areas of core activity should, according to Petit, not be a matter for concern, if the undertakings in question are 'moligopolies' and therefore are subject to a 'multidimensional degree of moligopoly competition'⁸⁰². This 'moligopoly screen' is sufficient to absolve any indication of likely anticompetitive effects on a relevant market, if firms-related variables provide the impression (or is it certitude?) that the firm is 'worthy' of the indulgence of finding no competition law violation, because (i) it is a conglomerate, (ii) it is open to experimentation, (iii) it is committed to patient capital, or (iv) is 'a platform leader, in other words...it serves as the foundation of an ecosystem of innovative companies'⁸⁰³. The paper builds this argument on the empirical finding that, contrary to monopolies, moligopolies 'channel sizeable amounts of resources into research and development' and invest in human resources (in particular entrepreneurship).

Despite its reference to a multidimensional framework for assessing competition and the criticism to the 'crude tool' of market definition, which we share, there are important

798 Ibid., 7-15.

799 Ibid., 39.

801 Ibid., 4.

802 Ibid., 65.

803 Ibid., 65-66.

problems with the overall argument of the paper and the ‘moligopoly screen’. First, Petit while criticising the traditional understanding of antitrust, relies on the simple economics of market definition in claiming that moligopolies increase production (and therefore output), which is something that cannot be wrong in his view, in particular as they also distribute this output ‘for free’. This may be true with regard to one side of the platform (e.g. search), but is not always true with regard to the other side of the platform (predictions, advertising), which is conveniently ignored, the paper falling in the single relevant market phalacy. In fact, there may be significant consumer harm in increasing the harvesting and exploitation of personal data, not only because consumers may be charged higher prices, than what would have been the case if they could not be targeted, but also because of the risks of manipulation and lessening of privacy. Second, the investment in R&D in these dynamic industries is certainly a positive feature, but as we have previously explained its level is lower than in other industries and is in no sense remarkable for a sector that has a high profitability and incurs less fixed costs and probably risks of failure than the pharmaceutical industry when launching a new molecule. Third, although the paper makes references to the fact that ‘moligopolies’ retain their earnings and do not distribute, this is not supported by the facts, which show that the top Big Tech distribute more to shareholders or to their management than what they invest in R&D (see Section 4.3.1.2.3.). The paper does not engage with the financialisation of US based digital platforms, which to a certain extent influences their competitive strategy, and may explain their development (and the formation of conglomerates) according to the ‘expand and distribute’ model. Fourthly, the paper assumes that ‘moligopolies’ are the sole source of R&D and innovation, and on the basis of this assumption, gives a *carte blanche* to them for regulating their ecosystems as they seem fit, suppressing innovative startups and reducing opportunities for vertical (innovation) competition. Fifthly, and most importantly, the paper does not engage in a true multi-dimensional analysis of competition, in particular by integrating the dominant characteristic of financialised capitalism, futurity and its role in competitive strategies. As we explained in 4.3.1.3., one needs to understand that competitive strategies do not only take place in product or service markets, or in fictitious markets for ‘entrepreneurship assets’ and ‘non consumption’, but also in financial markets where market evaluation of companies’ stocks because of the perception that they control a valuable bottleneck that may provide them with a sustainable competitive advantage and abnormal profits in the medium to long-term are crucial drivers for strategic action by the management. Certainly, the process of ‘convergence’⁸⁰⁴ of the IT, communications and AI may unleash some intensified degree of potential competition (and produce overlaps generating rivalry), but this remains for the time being limited. Despite the important convergence between the communications and IT industries in the last two decades, at the level of the core network layer used, with packet switched technology and LTE used for both IT and communications, each industry has kept its own service layer, its own private governance

804 Competition Commission of South Africa, [Data Market Inquiry Provisional Findings and Recommendations](#) (April 24, 2019), 180, notes ‘the convergence of various types of technology onto the same platform (e.g. video, voice, data) or the convergence of fixed and mobile devices (e.g. hybrid devices)’.

architecture and business models⁸⁰⁵, and is subject to different regulatory regimes with regard to the harvesting of data⁸⁰⁶. Hence, expecting competition clashes to occur in the short-term, this justifying a laissez-faire regime, seems ambitiously optimistic.

4.3.4. Sources of sustainable competitive advantage in the digital economy

There are various factors driving competitive advantage in the digital economy. In view of the high costs for the development of technologies and the need for these to inter-operate so as to provide the user a seamless experience, and the central role of 'system interconnectors', there is a high intensity of interaction and cooperation, as well as competition, between the different economic actors. Hence, the quest for competitive advantage takes more complex forms and the strategies are often quite elaborate, combining elements of cooperation and elements of competition (co-opetition⁸⁰⁷). We explore in great detail the sources of sustainable competitive advantage in the digital economy in Annex 2.

4.4. Moving beyond traditional relevant markets

The Internet era gave rise to many online intermediaries and digital platforms controlling and orchestrating value-generating ecosystems that not only offer products and online services but also provide the infrastructure and tools on which other platform businesses are built. At the same time, the development of Big Data and multi-sided markets strategies have raised questions and cast doubt on the sole focus of the assessment undertaken by competition law concerning the definition of the relevant market. How could one proceed to delineate a market in a world in which the possible personalisation of production means that consumers can themselves become the designers of

805 Compare the harvesting of personal data by Facebook and Google so that they offer social media and search engine services 'for free', with the approach used by AT&T which imposed a privacy surcharge in its GigaPower gigabit-speed broadband Internet service, offering consumers an option to prevent AT&T from collecting vast amounts of data about its users' browsing habits for advertising and other purposes: see Elizabeth Dwoskin & Thomas Gryta, AT&T Offers Data Privacy—for a Price, available at <https://blogs.wsj.com/digits/2015/02/18/att-offers-data-privacy-for-a-price/>. The programme was later abandoned: see <https://www.fool.com/investing/2016/10/03/att-drops-its-controversial-extra-charge-for-privacy.aspx>.

806 An interesting example concerns the regime regulating the harvesting of personal data. While social networks and search engines are free to harvest all sorts of data, although now in conformity to the GDPR rules, this may not be possible for mobile operators which, [until Congress adopted resolutions to repeal the broadband privacy regulations introduced in 2016 to reverse the Broadband Privacy Rule, a regulation from the FCC that made some inconvenient changes to the ways internet providers can collect and sell the data they collect on consumers], could not harvest data from the websites visited, emails and other texts and with some limitations could only collect location data. Note however that in March 2019, the FTC issued orders to seven U.S. Internet broadband providers seeking information to examine how broadband companies collect, retain, use, and disclose information about consumers and their devices: available at https://www.ftc.gov/system/files/attachments/press-releases/ftc-seeks-examine-privacy-practices-broadband-providers/isp_privacy_model_order.pdf.

807 A Brandenburger and BJ Nalebuff, Co-opetition (Currency Doubleday, 1997). Professors Brandenburger's and Nalebuff's concept of 'co-opetition' may characterize the future of competitive interactions in the economy, where business become more competitive by cooperating with each other and developing unique capabilities that add value and complement those of their competitors.

the individually-customised products they consume with the products being produced by 3-D printing and robots? Will firms be competing mainly on the market for personal information? What will serve as the raw material on which personalised production will be based? Competition law analysis needs to consider, when assessing competitive constraints, the type of competition taking place in the specific 'field'. We consider that the current field of relevant market is too simplistic and will have to be complemented by additional fields of assessment of the competitive game.

4.4.1. Multi-sided markets and 'transaction platforms'

Platforms that operate in multi-sided (often two-sided) markets facilitate the interaction between two groups of customers, where members on each side are more willing to 'be on board' if they expect the other side to be equally popular (matching platforms). Classic examples are:

- credit cards, where users want a card that is accepted ubiquitously, and merchants do not want to lose business by not offering to their client the convenience of being able to pay with their credit card;
- online marketplaces (e.g., auction sites): where both sellers and buyers are keen to trade in a tick market with plenty of choice;
- game consoles (and App [application] stores): where users want a variety of compatible games (Apps) and game (Apps) developers do not want to waste their energies developing a game (App) for a proprietary platform unless it is expected to attract many potential clients.

What these examples share is the fact that members from each side join the platform to execute an interaction (often carry out a transaction) with a member from the other side – i.e., the platform is a match-maker. Hence, a decision of a member to join the platform on side A will benefit members on the other side B; and vice versa, in the sense that to the extent that side B becomes more attractive (thanks to the new affiliation on side A) this will in return increase the utility of joining side A in the first place.

In economic jargon these cross-sided dynamics are called 'indirect network externalities', as opposed to 'direct network externalities' where there is only one side and users benefit if other users join the network – e.g., mobile telephony. The term 'externality' refers to the idea that, when an individual user decides to join in, he/she will normally fail to appreciate that his/her decision will benefit others (either on the same side under direct network externalities, or on the other side as with multi-sided platforms).

Hence, the theory goes, individual adaptations should be encouraged through some form of subsidisation in order to achieve the optimal critical mass on the network. Accordingly, the role of the two-sided platform is to 'internalise' these externalities, by solving the 'chicken-and-egg' problem that typically besets such platforms thus managing to get 'both sides on board'. This is typically done by subsidising the side that at first brings

the strongest benefits to the other side, e.g., women's entrance in a night club, users' access to a property website (whilst estate agents are charged to list their properties). Therefore, the fees charged on both sides may not reflect the underlying costs incurred for each side.⁸⁰⁸ Indeed, one side might not be charged at all, or even there could be negative prices on one side to bring them on board – e.g., a free voucher.⁸⁰⁹

These peculiarities make it tricky to implement the SSNIP test. To impose a SSNIP only on one side, would ignore the fact that a reduction in membership (i.e., following an increase in the membership fee) or intensity of usage (i.e., due to an increase in the transaction fee) on one side will cause a similar knock-on effect on the other side and so on. That is to say, indirect network externalities provide a constraint on the ability to impose a SSNIP on one side only. Therefore, it is argued that the hypothetical monopolist should be required to increase the overall *level* of prices, whilst allowing the platform to adjust the *structure* of prices across each side in order to minimise the negative feedback loop thereof.⁸¹⁰ Incidentally, the interrelatedness between the two sides strongly points towards a two-sided market definition, whereby substitutability is based on the same idea of match-making between the two sides.⁸¹¹

The analysis of two-sided markets/platforms presented so far is uncontroversial, in the sense that there is little doubt that the examples presented above fit the concept. However, there is a tendency to stretch the definition of two-sided markets, as by doing so it is possible to argue that antitrust intervention is unwarranted since the ability to exercise market power is naturally constrained by the kind of negative feedback loops (fuelled by indirect network externalities) described above.⁸¹²

In particular, media markets are regularly considered to be two-sided markets *sui generis*, where on one side there is the audience (readers/listeners/viewers) and on the other side there are advertisers seeking to reach that audience. However, media markets definitely constitute an outlier in terms of their presupposed two-sidedness for at least three reasons:⁸¹³

808 There can two types of fees: a) membership fee to just become an affiliate; and b) transaction fee, levied each time an interaction with a member of the other side is executed.

809 This is typically the case where the members of one side are promiscuous, in the sense that they can use multiple platforms, often at the same time (so-called, 'multi-homing').

810 For a discussion on this topic, see L. Filistrucchi, D. Geradin, E. van Damme and P. Affeldt (2013), 'Market Definition in Two-Sided Markets: Theory and Practice', (2014) 10(2) Journal of Competition Law & Economics 293.

811 This does not mean that only platforms can be seen as potential substitutes. For example, transactions do not have to be intermediated, as with cash payments in place of the use of credit cards. For a discussion see, Chapter 4.

812 In contrast, though, two-sided markets may be subject to 'winners-take-all' dynamics, where the incumbent platform becomes the de-facto place to be for users on both sides. Therefore, the chances of rival platforms being able to build their own critical mass are low due to an insurmountable 'chicken-and-egg' problem. The role of network externalities as potential barrier to entry and expansion is discussed in the next section.

813 For a detailed discussion, see G. Luchetta, 'Is the Google Platform a Two-Sided Market?', (2013) 10(1) Journal of Competition Law & Economics 185.

- indirect network externalities are only one directional, rather than reciprocal: advertisers benefit from larger audiences, but not vice versa. Indeed, ads normally constitute a nuisance for the audience;⁸¹⁴
- the two sides do not interact on the platform. It is true that the aim of advertisers is to ultimately trigger a transaction, but none of this is hosted by the platform – i.e., the primary purpose for the audience to affiliate the media outfit is to access content, whilst tolerating advertisers' attempt to build brand awareness;
- for media firms two-sidedness is an optional business model, not a necessity – i.e., their core business is not about match-making in nature. For example, a TV operator can either adopt a free-to-air business model – where content is free for the audience whilst advertisers pay to have their ads aired – or a Pay-TV business model – where the audience has to pay to view content of their choice, often without the nuisance of advertising.⁸¹⁵

By the same token, it is debatable whether social networks, such as Facebook and Twitter, and search engines, such as Google search, are truly two-sided platforms. In both cases usage is driven by the desire to interact, respectively, with other users (i.e., direct network externalities), or finding the right content on the web for free, whilst tolerating the fact that their data are used by the host operator to allow advertisers to target them with their impressions (i.e., the externality is one-directional rather than reciprocal).

Accordingly, in all these (*sui generis*) cases, to impose a SSNIP on advertisers would hardly set off the kind of negative feedback loop described above. The ability to exercise market power on one side is not restrained by the need to keep both sides on board, since the audience would not be bothered by the fact that there is less advertising on the platform (i.e., as a consequence of an increase in price). It is true that the ability to offer, potentially for free, good quality content and online services, such as search and social networking, relies on the monetisation of audience's attention, but the audience decision as to of which services to use is not affected by an expectation that the other side will be popular.

That is to say, there is no 'chicken-and-egg' problem, in that it is the quality of the content provided (for free) that determines audience's affiliation, and advertisers do not determine the quality, they only exploit it (at a price) in order to reach their target audience.⁸¹⁶ As a final example, let's consider price comparison sites, which are free to con-

814 There are exceptions, of course, as with readers of fashion/glamour magazines and with classified ads. In the latter case, though, advertisers have radically deserted media outfits and, nowadays, normally prefer to reach the other side by posting their ads on dedicated two-sided platforms such as gum-tree, eBay and many others.

815 It is true, of course, that a Pay-TV business model would not be viable without premium content such as sports and recent blockbusters, but the choice of what type of content to broadcast is endogenous, in the sense that an FTA TV operator could over-time decide to switch to a Pay-TV business model.

816 One peculiar feature that distinguishes media business from social networking and web-searching is that in the latter case the quality of the content is determined in a positive way by the number of users (i.e., positive direct network externalities). For example, Google's search engine gets better and better thanks to the cumulated intelligence gathered as to what constitute a good search result. Hence, the importance to maintain high volume of traffic.

sult for user whereas sellers are charged, typically, a commission on a per-click basis. On the one hand, users look for a comparison that is both accurate and covers the entire market (e.g., car insurance quotes); on the other hand, sellers are in two minds, as they want to be listed on popular websites but are aware that accurate comparison spurs pricing rivalry.

Usually, though, sellers have no choice as they know that the website may list their offer in any case. This is the key intuition as to why price comparison sites are not two-sided platform in a strict sense: users' decision to consult is based on the expectation of a comprehensive and accurate comparison, regardless of whether sellers accept to be charged for sponsored links or on a click-through basis. Indeed, the fact that price comparison websites are financially reliant on sellers' commission fees makes users uneasy, if not suspicious; and this is notwithstanding the fact that users would hardly pay for a comparison that is financially independent.⁸¹⁷

In conclusion, whilst it is important to be aware of the type of unidirectional externality that characterises these types of (*sui generis*) platforms, a one-sided approach to market definition may nevertheless still be appropriate.⁸¹⁸

This is still the approach followed by the EU Courts, which usually address the issue of multi- sidedness not when they determine the competitive constraints directly faced by the undertaking in question in defining the appropriate antitrust relevant market that will serve as the starting point for competition assessment, but when determining the existence of a restriction on competition, since the two- sidedness is part and parcel of the overall economic context that needs to be taken into account by the competition decision- maker before concluding on the existence of a restriction of competition by object or by effect⁸¹⁹. In contrast, in a five to four judgment in *Ohio v American Express Co*, drafted by Justice Thomas, the majority of the US Supreme Court highlighted the fact that some two- sided platforms, such as credit card operators like American Express, facilitate a single, simultaneous transaction between merchants and cardholders and thus supply 'only one product', namely transactions, which are jointly consumed by the card- holder and the merchant⁸²⁰. The Supreme Court stressed the importance of evaluating *both* sides of a two- sided transaction platform in order to accurately assess competition and thus analysed the two- sided market for credit-card transactions as a whole, at least for 'transaction platforms'⁸²¹.

817 For a detailed discussion, see H.C. Gamper, *How Can Internet Comparison Sites Work Optimally for Consumers?*, (2012) 35 *Journal of Consumer Policy* 333-353.

818 See L. Filistrucchi, D. Geradin, E. van Damme and P. Affeldt (2013), 'Market Definition in Two-Sided Markets: Theory and Practice', (2014) 10(2) *Journal of Competition Law & Economics* 293. For some examples of cases in the UK where multi-sided markets were considered, see *Global Radio/ GMG* (CC, 2013); *WRI/Hostelbookers.com* (ME/6062/2013); *BSkyB/ Virgin Media* (ME/4568/2010); *Capital Shopping Centres/Trafford* (ME/4903/2011).

820 *Ohio v American Express Co*, 585 US _ (2018).

821 According to the majority Opinion, the key feature of transaction platforms is that they cannot make a sale to one side of the platform without simultaneously making a sale to the other. This approach was criticized by the minority of the Supreme Court in an Opinion drafted by Justice Breyer, who considered that the relationship between merchant- re-

Box 4.4. Market Definition and the digital economy – A BRICS perspective

BR Market definition is a challenging task in the digital economy. In digital markets there are some particularities that should be taken into consideration, which are not explicitly established by any guide or legislation, but that have been revealed by the academic literature and examined in past cases analysed by CADE. In general, CADE holds that the Brazilian legal framework provides enough flexibility to adapt the existing concepts and tools. Therefore, the current toolkit has been suitable to analyse the cases involving digital market that CADE has investigated so far. Nonetheless, CADE also recognises that due to the rapid pace of innovation and transformation of the digital economy, legal and economic concepts employed by competition policy need to be constantly studied and reviewed. In that sense, CADE is developing studies to identify whether the current competition framework and tools of enforcement should be updated and adapted.

RU The ‘fifth antimonopoly package’ proposes to introduce the data ownership as a criteria for market definition.

ZA How markets are defined for the purpose of determining market shares and market power is not given specific expression in the Competition Act and is therefore subject to the application of economic techniques to the available evidence. These economic techniques include the necessary tools for defining digital markets such as two-sided assessments. As such, the current legislation is adequate for purposes of market definition. Problems may arise in instances of potential entry because authorities normally base their views on information on existing competitors. However, in digital markets, there is a significant role played by disruptive technologies such that the market may not always be limited to the relative positions of competitors at a given point in time, but competitors coming from outside are also relevant. For example, Uber came from outside the metered-taxi market to disrupt the metered taxi business when nobody was expecting it.

4.4.2. From ‘Big’ and ‘Smart’ Data and ‘matching’ platforms to prediction platforms

4.4.2.1. Data and Big/Smart Data markets

Competition authorities and the largest body of scholarly work on digital platforms has focused on competition law issues related to the harvesting and possession of data

lated card services and shopper- related card services is primarily that of complements, not substitutes, and thus the two could not form part of the same product market. Justice Breyer rejected the concept of ‘transaction platform’, *inter alia*, because of the difficulty to determine its limiting principles and to distinguish clearly these platforms from other platforms in which the two sides should be considered separately. The approach of the minority of the US Supreme Court seems close to that adopted by the CJEU in *Cartes Bancaires*.

from digital platforms, in particular access to personal and/or non-personal big data issues. The concept of ‘big data’ is usually employed to refer to gigantic digital datasets, which are often held by corporations, governments and other large organisations, and which are extensively analysed using computer algorithms.⁸²² It is thought that access to data may become a source of market power: according to a joint report by the German and the French competition authorities, ‘(p)rovided that access to a large volume or variety of data is important in ensuring competitiveness on the market (which is a market-specific question), the collection of data may result in entry barriers when new entrants are unable either to collect the data or to buy access to the same kind of data, in terms of volume and/or variety, as established companies’⁸²³. This data may be either provided voluntarily by the consumer or prospective customers of a company in the context of existing transactions or attempts to enter into these transactions, it may be observed or inferred and aggregated by the digital platform in the context of an interaction with a (prospective) customer, in these cases the undertaking having control on the collection of data as it is involved in the relationship with the (prospective) customer (thus constituting a ‘first party data’ source). The fact that some undertakings benefit from a considerable market share in terms of number of users leads them to also benefit from a large share in the harvesting of data. Furthermore, undertakings may also use ‘third-party data’, that is ‘data collected by another entity’, although this possibility may be limited by some regulatory restrictions on the transfer of data between first and second aggregators (i.e. data protection requirements on consent)⁸²⁴. In these cases, it is possible that superior access to data could provide a competitive advantage and could increase barriers to entry isolating ‘established competitors from smaller rivals and potential entrants, thereby allowing them to increase their prices’⁸²⁵. Consequently, a lot of the discussion has focused on ways to reinforce inter-platform competition by promoting access to data and data portability. We will discuss these efforts in detail in subsequent Chapters of this report.

With regard to delineating relevant markets for the sale or purchase of data, one needs to distinguish between situations in which the data operates as an input for a product and is not traded or sold to third parties, in which case it would be difficult to define a pure data market and the competition authorities proceed to a ‘market determination based on the services provided’⁸²⁶, and situations in which data is available to be traded

822 ‘Aspects of ‘big data’ that are often mentioned are large amounts of different types of data, produced at high speed from multiple sources, whose handling and analysis require new and more powerful processors and algorithms’: Autorité de la Concurrence & Bundeskartellamt, Competition Law and Data (May 16, 2016), 4. ‘Big data’ is often characterized by the various ‘V’s’, which go from four, according to certain descriptions, Velocity, Variety and Volume, Value (to be extracted) to six, according to others adding Veracity and Validation.

823 Autorité de la Concurrence & Bundeskartellamt, Competition Law and Data (May 16, 2016), available at https://www.bundeskartellamt.de/SharedDocs/Publikation/DE/Berichte/Big%20Data%20Papier.pdf?__blob=publicationFile&v=2, 11.

826 For a discussion, see I. Graef, Market Definition and Market Power in Data: The Case of Online Platforms, (2015) 38(4) World Competition 473, 491 (discussing the Facebook/WhatsApp acquisition, where the Commission did not define a

or sold to third parties, in which case it would be possible to define a market for the provision of data, as a 'specialised asset'⁸²⁷. However, the last option is usually fraught with difficulties. For instance, in the recent *Apple/Shazam* merger, the European Commission found that both parties were active in the licensing of music data (in particular music charts data), among other relevant product markets. The Commission explored the degree of substitutability (or complementarity) between the parties' different data products, in particular their music data charts. The substitutability of the music data charts of Apple and Shazam was debated as there were differences between them that made them complementary rather than substitutable: for instance, Shazam's music charts could give an indication of the popularity of certain music tracks, as well as of future music trends, while Apple's charts reflected Apple's estimates of its own music sales and/or usage patterns⁸²⁸. The Commission did not find it necessary to determine this substitutability question as this did not affect the competition assessment. This did not refer to personal data, as the Commission did not find a horizontal overlap in relation to the Parties' user behavioural data, which was not in any case licensed by the Parties to third parties⁸²⁹.

When it came to determine the market shares of the parties in this market, the Commission was not able to compile market shares and found that there was a large number of sources of music data⁸³⁰. Interestingly, the parties contested the definition of a separate relevant market for music chart data, arguing that they were instead an 'ancillary feature of the core business of music streaming or voice recognition'⁸³¹. They also argued that should a separate data market be defined, this would have existed 'for the collection of data on individuals' music tastes and the analytics of such data' and should not have been limited to data collected in the digital music industry, but should have covered 'all data compiled relating to music preferences, including data gathered by undertakings active in the wider field of online social networks' (i.e. LinkedIn, Facebook, WhatsApp or Google) collecting the same type of data on their users. This argument was not accepted by the Commission, which preferred to define a separate market for music charts, although it did accept that there were multiple sources for such data. Interestingly, the Commission considered that, regardless of whether it constituted a relevant product market, access to this data could constitute a possible competitive advantage for the new entity as it could have helped it 'to improve existing functionalities, or offer additional functionalities'⁸³². This assessment formed part of the analysis of the non-horizontal unilateral effects of the transaction resulting from the possible foreclosure of

data market as none of the parties was trading or selling the data to third parties).

competing providers of digital music streaming apps, to the extent that user data is an important input for competing providers of digital music streaming apps⁸³³.

Box 4.5. The CADE analysis of big data

In 2016, CADE analysed a case in which Brazil's leading banks formed a joint venture for credit scoring. Credit scoring companies are multi-sided markets with strong network effects. Financial institutions are the main suppliers of inputs (information about users' financial transactions) to credit bureaux, while they are also the main consumers of bureaux's products (credit scores). Thus, CADE was concerned the operation would lead to vertical integration. In this case, CADE analysed whether data (information about consumers) might act as an entry barrier. When data is also a source of market power, a dominant platform can leverage its userbase in order to prevent potential competitors to enter the market, which might lead to market foreclosure. The SG and the Reporting Commissioner highlighted the risks of foreclosure in both the markets of positive and negative credit scoring, due to the great number of consumers' data held by the proposing banks. Accordingly, one of the remedies agreed by the parties was the commitment that the banks would continue providing data to all credit bureaux, with no discrimination or provision of favourable treatment to their own bureau.

Source: BRICS NCAs Questionnaire

The activity of digital platforms relies on the harvesting and processing of different types of data, which may constitute, under certain circumstances a source of market power or dominance. In particular user data may be a source of increasing returns, due to either economies of scale and scope or learning effects to the extent that more user data may enable the digital platforms to train better the algorithms underlying their services, in particular as platforms present in several markets may harvest data from different markets, thus forming a 'richer model of consumer (behaviour)' (economies of scope)⁸³⁴. The possession or control of data for which there is no good substitute may also enable a digital platform to raise the costs of its rival platforms or make it more difficult for them to compete in advertising markets, by adopting exclusionary conduct, such as refusals to deal, exclusive contracts with third party data brokers or aggregators who could have been an alternative source of data for their rivals, or erecting barriers to data portability for its users⁸³⁵. Digital platforms may also adopt predatory conduct limiting the ability of competing platforms to reach a critical mass of users that would enable them to benefit from network effects⁸³⁶. This, for instance, may occur if the platform uses as bait to attract users free products or below AVC prices in one side of the platform (the 'honey'). The harvesting and control of data may also enable the development of sophisticated pricing practices, in particular price discrimination, or of strategies in-

833 CASE M.8788 – APPLE / SHAZAM (2018), Section 8.4.2.2.

834 M. L. Katz, Multisided Platforms, Big Data, and a Little Antitrust Policy, (2019) Review of Industrial Organization, available online at <https://doi.org/10.1007/s11151-019-09683-9>

835 Ibid.

836 Ibid.

creasing switching costs for consumers giving rise to lock-in effects of the consumers to specific platforms⁸³⁷. Access to data may also increase information asymmetry between undertakings or between undertakings and consumers, thus enabling the undertakings (or digital platforms) with privileged access to reinforce their bargaining power vis-à-vis other undertakings or the consumers, with the potential to limit consumer surplus.

However, it may be also argued that, in a lot of cases, data presents some of the characteristics of a public good, to the extent that their consumption is non-rivalrous, and there may also be different sources of data available, in particular if data is traded or sold on data markets. The availability of data in the digital economy, and the multiplication of data harvesting devices, in particular with the development of the Internet of Things, is put forward as an argument to challenge the conception of data as posing a barrier to entry or as forming an essential facility⁸³⁸. A lot of user data is presumably available through data brokers (third parties), such as Acxiom, Experian, Epsilon, CoreLogic, Datalogix, inome, PeekYou, Exactis, Recorded Future, among the more than 4000 data brokering companies worldwide. Contrary to other digital intermediaries, these do not provide any products or services to the consumer, their core business being to harvest data and to trade/sell it to other firms⁸³⁹. Digital intermediaries or suppliers, such as Oracle, Thomson Reuters, IBM, Nielson Holdings Plc, Bloomberg, Moody's, Alibaba Wolters Kluwer etc., may also be present in the data brokerage market, and sell data in their possession. Data brokers detain considerable information. For instance, Acxiom, one of the major data brokers, provided up to 10000 attributes on 2,5 billion of consumers in 2018⁸⁴⁰. However, it has also been noted that this data is kept in 'silos', according to the sector of activity (e.g. Experian and Epsilon is focusing on data that are relevant for marketing), the companies having mostly a vertical focus usually not addressing the full range of the data transactions⁸⁴¹. This data, which can be on consumer purchase and transaction information, consumers' available methods of payment, health conditions, social media activity is harvested through mainly 'five major avenues: government records and other public data, purchase or license from other data collectors, cooperative

agreements with other companies, self-report by consumers, often through surveys, questionnaires, and sweepstakes, and social media⁸⁴². These data brokers use this data to create products and services providing customers with data that has varying degrees of specificity about individual consumers, either on the basis of ‘actual’ elements of information, or on the basis of ‘modeled’ data that result ‘from drawing inferences about consumer characteristics or predicted behavior based on actual data’⁸⁴³.

The issues raised by the privileged or unique access of some digital platforms to valuable data raise the possibility of competition law intervention in order to limit the likelihood of exclusionary practices.

4.4.2.2. Attention markets

Emphasising control over data and defining separate data markets may however overlook the real competitive game in the platform economy. Data, as such, may not be the core aspect of the business model, in particular of the leading digital predictive platforms relying on an advertisement-based model (i.e. Google, Facebook).

These platforms aim to attract and hold the attention of the users, not only in order to harvest data, but also more generally in order to influence their choice and manipulate their preferences through a some (insidious) process of choice architecture. In the classic two-sided model of digital platforms, these platforms are thought as matching, on one side, advertisers (the money side) and users (on the subsidised side). Data harvesting is indispensable for this process of matching to work. However, in reality, the digital platforms do not trade or sell access to the raw data of the users, which stay the possession of the digital platform, but simply sell information, that is *inferences* from the data the digital platform was able to harvest *and* process on the personality of the consumers and their overall preferences. This mapping could be relevant for the specific product/service the advertiser is aiming to promote. Advertisers value a lot these inferences, to the extent that they know these are quite accurate and enable them to offer targeted advertising that would be more likely to attract the attention of the users on the products/services they promote. From this perspective, data is an indispensable input for an output sold in ‘attention markets’.

Contrary to data, which may be available from a variety of resources and is a non-rivalrous resource, attention is a scarce and rivalrous resource, to the extent that an individual has a limited attention span. As a result of the digital revolution and the systematic use of smartphones, individuals receive increasing amounts of information, which recent

842 US Senate, Committee on Commerce, Science and Transportation, A Review of the Data Broker Industry: Collection, Use and Sale of Consumer Data for Marketing Purposes (2013), 15 (although the Report noted that some of the major data brokers did not share information on their main data sources); US FTC, Data Brokers: A Call for Transparency and Accountability (May 2014), 11-15.

843 Ibid., 23-35 (noting three broad categories of products: marketing, risk mitigation, such as identity verification or fraud detection, and people search).US Senate, Committee on Commerce, Science and Transportation, A Review of the Data Broker Industry: Collection, Use and Sale of Consumer Data for Marketing Purposes (2013), 22. Actual data may be used to create ‘look-a-like’ models from predicted characteristics of types of users.

research has found lead to a narrowing of their collective attention span⁸⁴⁴. Attention is a scarce resource that may be easily exhausted in an information heavy ‘always connected’ environment. As Satya Nadella, the chief executive officer of Microsoft, wrote in a recent report ‘(w)e are moving from a world where computing power was scarce to a place where it now is almost limitless, and where the true scarce commodity is increasingly human attention’⁸⁴⁵. Professor Tim Wu at Columbia University Law School claims that ‘(o)ver the coming century, the most vital human resource in need of conservation and protection is likely to be our own consciousness and mental space’⁸⁴⁶. Research by Microsoft Canada indicates that the average human attention span went down from 12 seconds in 2000 to 8 seconds in 2012, less than the average attention span of a goldfish!⁸⁴⁷

The development of ‘addictive technologies’, such as smartphones have considerably reduced the attention span of younger generations, in comparison to older generations. Empirical research has documented the ‘accelerating dynamics’ of shorter attention cycles that has been mainly driven by ‘increasing information flows’ both in terms of content production and consumption rates through the use of smartphones⁸⁴⁸. The result is ‘shortening attention spans for individual topics and higher turnover rates between popular cultural items’, leading to the ‘squeezing of more topics in the same time intervals as the result of the (consequent) limitations of the available collective attention’⁸⁴⁹. Indeed, the research by Microsoft Canada indicated above notes that higher usage of social media ‘increases short bursts of high attention’⁸⁵⁰. These scarce period of ‘high’ ‘attention bursts’⁸⁵¹ are therefore extremely valuable for advertisers and/or companies and other entities aiming to attract consumers’ attention and influence consumer behaviour. Some media may be more efficient than others in attracting this attention.

Sohlberg and Mateer’s well known theoretical framework for analysing attention distinguishes five different components of attention on the basis of the clinical model of attention based on experimental attention literature⁸⁵² (see Table 4.2.).

852 M.M. Sohlberg & C.A. Mateer, *Cognitive rehabilitation: An integrative neuropsychological approach* (Guilford Press, 2001).

Table 4.2.: Varieties of attention

Component	Description
Focused attention	Response to discrete visual, auditory, or tactile stimuli
Sustained attention	Vigilance and working memory
Selective attention	Ability to ignore irrelevant or distracting stimuli
Alternating attention	Set shifting, mental flexibility
Divided attention	Ability to respond to multiple simultaneous tasks

Source: M.M. Sohlberg & C.A. Mateer, Cognitive rehabilitation: An integrative neuropsychological approach (Guilford Press, 2001).

Following this model, research by Microsoft Canada examined how our increasingly digital lives may affect three components ('types') of attention from those enumerated above: in particular, sustained, selective and alternating attention.

First, with regard to sustained attention, the research notes that that exposure to increased digital consumption through social media usage erodes long-term focus⁸⁵³. Indeed, social media users, which is a large and increasing part of the human population, pay more attention in interactive (digital) environments, their results being also high with regard to connection (emotional attachment) and encoding (memory). The research emphasises how overall, 'digital lifestyles have a negative impact on prolonged focus'⁸⁵⁴. As a result, consumers are trained to become better at processing and encoding information through these highly valuable 'short bursts of high attention'⁸⁵⁵.

Second, digital lifestyles also have implications on selective attention. A number of similar devices (PCs, smartphones, tablets or combinations) have become the 'gatekeepers of an infinite number of distractions and sources of instant gratification', but also important gateways to consumers' attention. Users attempt to simplify their lives by disconnecting or switching off these devices, expressing their wish to filter out distractions⁸⁵⁶. This need for simplification leads to the finding that '(w)hat consumers can see in one glance has everything to do with what they'll do next'⁸⁵⁷. Again, this has important implications on companies' strategies to attract attention and indicates the existence of important leverage and tipping points for attention.

857 Ibid., 33.

Third, although an active engagement with social media may build alternating attention and train users to multi-tasking, when this use crosses the top quartile, social media drain resources and reduce the ability of users to allocation attention, 'connect with content on an emotional level, and process information'⁸⁵⁸.

Attention can be captured in different ways, depending on the form of the 'attentional decision' of the user⁸⁵⁹. In reviewing the attention scholarship, Tim Wu distinguishes broadly between two different mechanisms for making these attentional decisions: the first is when attention can be seized in voluntary manner, and the second when attention is captured without a voluntary decision being made by the agent⁸⁶⁰. He includes in the second category 'bottom-up' or 'stimulus-driven' attention 'activated by lower parts of the brain outside of conscious control', to the extent that our brains are 'involuntarily responsive to properties inherent in certain forms of information' or stimuli (e.g. food, familiar faces, potential sexual partners)⁸⁶¹.

These different mechanisms to capture attention, sometimes involuntarily, are well known by the 'management of specific demand industry', whose purpose is to 'shift the locus of decision in the purchase of goods from the consumer where it is beyond control to the firm where it is subject to control'⁸⁶². This includes according to the description given to it by John K. Galbraith, not only the advertising industry but also 'a huge network of communications, a great array of merchandising and selling organizations', 'numerous ancillary research training and other related services'⁸⁶³ in these economics of 'increasing affluence'⁸⁶⁴ but also of limiting attention.

What has changed with the emergence of digital platforms and superior technologies of personalisation is that instead of this management of demand being targeted to the mass, it is now possible to target it to the individual consumer. By selling attention and enabling targeted advertising, digital platforms also contribute and form part of this 'management of specific demand industry'.

In a recent working paper, Andrea Prat and Tommaso Valletti formalise the ability of digital platforms to sell personalised advertising to product market firms.⁸⁶⁵ Prat and Valletti propose that usage data held by digital platforms provides them with proprietary information on the activity of users, to which the platforms apply artificial intelligence in order to infer consumption preferences of individual users.⁸⁶⁶ Acting as 'attention

866 As per Ajay Agrawal, Joshua Gans and Avi Goldfarb, The Simple Economics of Artificial Intelligence (Harvard Business

brokers', the platforms then sell, via auction, targeted advertising to the firms that supply the product or service the user is interested in. Given the scarcity of attention noted above, platforms become 'attention bottlenecks', through which they control access to consumers.⁸⁶⁷

Moreover, it is the largest digital platforms, including Google and Facebook, that are best able to match consumers and advertisers due to the scope, scale and timeliness of the data they collect and analyse. Access to such personalised advertising, through the platform-bottleneck, may play a significant role in maintaining or establishing market power for retailers.⁸⁶⁸

Indeed, in line with Prat and Valletti's narrative, the business model of some of the leading digital platforms relies on advertising revenue, collected at the money side of the platforms, which partly subsidises the content received by users on the other side, to the extent that users do not pay a monetary price (free content). Users may pay a price in a reduction of their privacy, as their personal data is harvested by the platform. As indicated above, this data is used as input for the delivery of the services of digital platforms, the inferences as to the users' preferences and personality that would enable the advertisers to target them better. The business model is particularly ingenious as the 'free' content from which the consumers may benefit, and which acts as bait (the 'honey') to attract their attention, at the same time adds to the information they receive and therefore narrows down their attention span. This makes the attention of the users even more valuable for advertisers, which are then ready to pay increasingly high amounts for their ads to be placed at a more valuable attention grabbing position, or for benefiting from specialised advice on what would better attract a specific user's attention. This process of value extraction therefore is self-reinforcing as it contributes to the scarcity of attention that generates the surplus value captured by the various business actors involved in this process. Hence, competition is not really for data but for the increasingly scarce resource of human attention.

This form of scarcity has its proper intermediaries: the so called 'attention merchants'⁸⁶⁹. One of the first manifestations of this new form of commerce is the emergence of printed advertising in the late 17th century in England⁸⁷⁰, and in the printing press in the early decades of the 19th century in England and the United States⁸⁷¹ as a way to finance the printing and distribution of newspapers below costs, to the extent that these were subsidised by the revenue made by selling advertising. Newspapers were indeed not relying

on the 'traditional strategy' for making profit, that of selling at a price that is higher than the cost of production, but on different business model, the reselling of the attention of their readers in advertising markets⁸⁷².

We consider that the field on which the assessment of competition takes place needs to be determined according to the broader conception of the competition game and in particular being related to the process of accumulation of capital and the capture of value in the digital economy. Hence, we need to explore more closely the value generation and capture process taking place in these 'attention' markets. An important issue with 'attention' markets is nevertheless to develop an appropriate metric that would enable competition authorities to prioritise their scarce resources and ensure that their intervention in these markets may be effective.

Digital advertising markets may provide indications as to the value of this attention captured by the digital platforms (by reference to some form of hedonic pricing). Digital advertising spending has risen considerably worldwide, from \$152 billion in 2015 to \$204 billion in 2017. Internet advertising spending worldwide is projected to rise to \$142,2 billion for display advertising, \$109 billion for advertising in search engines (paid search), and \$23,2 billion for classified Internet ads (\$274.4 billion)⁸⁷³. Most of this digital advertising revenue was collected in 2018 in the US (\$100.69 billion), followed by China (\$48.96 billion), the UK (\$12.74 billion), Japan (\$11.7 billion), and Germany (\$10.65 billion)⁸⁷⁴. Digital advertising is still however not the most significant source of advertising revenue. In the US, out of the \$191.2 billion total of the advertising market (all media), Internet/digital advertising occupied the second place in 2016, while TV advertising was ranked first, with much smaller parts going to radio advertising, newspaper and consumer magazines advertising and outdoor advertising⁸⁷⁵. The largest part (a little more than 60%) of the digital advertising revenue is collected through the use of mobile rather than desktop computing⁸⁷⁶. With regard to the US digital advertising spending per industry, more than 20% comes from the retail sector, followed by the automotive industry (12.6%), financial services (12.2%), telecom (10.7%), and consumer products (8,8%)⁸⁷⁷. Online advertising has also surged in Europe. In the UK, the largest market in Europe, online advertising accounted for 52% of total UK ad spend (most of this generated by mobile Internet use), followed by TV advertising (with a little more than 12% of the total UK ad spend), advertising being the main source of funding for online content⁸⁷⁸. Paid for search accounted for half of the online advertising, although display advertising

also made heavy inroads in recent years⁸⁷⁹.

The core activity of these advertising markets therefore consists in the capture of the attention of the users of digital platforms. The attention of users becomes a commodity that is freely traded and exchanged in attention markets. An important dimension of assessing the economic impact of the conduct of the rise of dominant digital platforms on the attention of consumers is to determine the value and the boundaries of these markets. The fact that attention can be valued results from its commodification and evaluation in the context of specific advertising markets. This can even go beyond taking the form of evaluation in fiat money, but embracing futurity even further, its value can be represented by a 'basic attention token' as this was issued in the context of the Initial Coin Offering of BAT, a token that can be exchanged between publishers, advertisers, and users in order to obtain a variety of advertising and attention-based services on the Ethereum blockchain run BAT platform⁸⁸⁰.

However, this metric faces several problems. Although the value the advertisers spend on digital ads is considerable, this only represents just a small part of the surplus value of the activity of attracting consumer attention, which forms the core activity of prediction platforms. This comes out of the routines that consumers have developed in using the Internet and specific digital platforms in their day-to-day life and the importance this continuous use has taken in the very short period of time of the explosive growth of the Internet that followed the diffusion of smartphones (and mobile Internet) since the launch of the iPhone in 2007. Some refer to this period as the decade of 'digital dependence'⁸⁸¹. As a recent report by the UK OFCOM (telecom regulator) explains, 'in an "always on" society, people expect to be connected everywhere through a plethora of devices'⁸⁸². The OFCOM report found that in a world where mobile phones are becoming ubiquitous, the time people spend online has considerably increased (in the UK it doubled on average from 12,5 hours in 2007 to 24 hours in 2018, while a fifth of adults, mostly the younger generations spend more than 40 hours each week online)⁸⁸³. Almost two thirds of adults (64%) in the UK agreed that the internet was an essential part of their life⁸⁸⁴. Consumers are always connected or feeling connected, the OFCOM report finding that '40% of adults first look at their phone (apart from checking the alarm/clock) within five minutes of waking up, increasing to 65% of under-35s. Even before going to sleep, 37% of adults check their phones five minutes before lights-out, again increasing to 60% of under-35s'⁸⁸⁵.

As previously mentioned this higher intensity of connectivity and use of the Internet is related to the rise in the use of smartphones, combined with the take-up of 3G and

879 Ibid., 78 (noting the increasing prevalence of video overtook banners for his type of ad format).

883 Ibid., 14.

884 Ibid., 15.

885 Ibid., 15.

4G networks improving the quality of connectivity, which enhanced mobile Internet access⁸⁸⁶. Smartphones offer a multi-functional device that usually combines functions previously completed by a range of devices. While the take-up of new technologies, such as smartphones, smart TVs, tablets or laptops has risen, other technologies, such as DVD players, Desktop PCs, MP3 players have seen their take-up decrease during this period, the smartphone becoming the more ubiquitous digital device.⁸⁸⁷ This ensures that the digital platforms controlling access to central points of control of control the vast amounts of information generated by Internet use. The use of new devices, such as smart speakers, whose functionality may be extended with software similar to smart-phone apps, or voice assistants is on the rise and would have considerable implications on the use of Internet as the devices are now controlled by the user's voice through an integrated AI voice assistant⁸⁸⁸. Voice control systems are also integrated in smart-phones, tablets, and certain models of smart TVs and even cars, and often provide the possibility of voice recommendations, further affecting the choice architecture of the user, as this does not have to choose on screen among different options but is instead 'suggested' an 'optimal' choice devised by the algorithm.

Accessing the Internet also becomes an activity that may be exercised outside work or home, the amount of time people spend online in a location other than work or home having quadrupled between 2007 and 2017⁸⁸⁹. An increasing number of people use their smartphone while commuting (the most frequent uses being sending and receiving text messages/ instant messages, accessing social networking sites and general web browsing)⁸⁹⁰. People use the Internet for entertainment, in order to avoid 'boredom', for shopping and online banking, as well as in order to stay connected with friends and family, although it is also acknowledged that being online may sometimes interrupt face-to-face communications⁸⁹¹.

Large digital platforms, such as Google and Facebook in Europe and the US, account for a very large amount of use of this important and increasing amount of time spent online⁸⁹². Figure 4.16. provides the list of the top 10 Internet properties accessed on mobile/desktop devices in the UK during March 2016 and March 2018. It appears in this Figure that Google sites (including You Tube, Google Search, Google maps, Gmail) and Facebook (including Instagram, Whatsapp and the main Facebook site) are ranked first and second properties with a considerably more intensive use, in terms of average time spent per person per month, than other websites.

886 The report notes that use of a smartphone increased from 27% of all adults in 2011 to 78% in 2018: Ibid., 16.

In this attention-seeking economy firms do not only compete for consumer expenditure, which may constitute the main incentive of firms present in advertising markets to be matched to consumers, but also, or sometimes instead, for consumer attention⁸⁹³.

Economic literature has explored different ways to value this consumer attention dedicated to online activities and the time spent on websites controlled by the major digital platforms.

As we have indicated, economists initially focused on the amount of money spent by advertisers, but this may under-represent the value of 'attention markets'. Other approaches started focusing on the time the users were spending on these platforms in an effort to assess the value provided by the Internet to consumers, which was difficult to assess under the traditional metrics as the services provided by these digital platforms were 'free', in the sense of 'zero-priced'. The ultimate purpose of these measurement efforts was to assess the value of the Internet⁸⁹⁴. Such evaluations were of course also related to the effort of determining the value provided by online ads to advertisers, publishers, charities and others, and were particularly important in the process of setting the auction technique that was used to value ads in the most popular digital platform in terms of number of users, Google⁸⁹⁵. Indeed, bidders compete through auctions managed by Google Ads for longtail keywords which may be most relevant for their target audience. However, they only have to pay if someone clicks on the ad (pay per click or

PPC) at the price set at the auction. Advertisers may predict how many clicks they will get at a new bid by using a Bid Simulator. This assumes of course that the value per click, generated for instance by the conversion of the click to, for instance, an online e-commerce transaction on the specific website, is greater than the incremental cost per click. In a widely publicised presentation in 2011 the chief economist of Google, Hal Varian, indeed indicated that advertisers on Google were getting back about seven times what they spent in value of ad clicks. They also had the possibility to benefit from clicks coming out of organic (non-ad funded search). While AdWords is focusing on the advertisers' side, AdSense focuses on publishers or Website owners helping them to reserve space for AdWords placements on their website (these could be text, video, images), the Google platform operating as an intermediary between advertisers and publishers/website owners. The latter get a 67% share of the ad revenue generated by AdSense. Varian also emphasised the benefits going to the users of Google's search engine in terms of time 'saved', estimating that this amounted to an annual value of \$120 billion in 2011, on the basis of the value of time savings to average users, but did not discuss any opportunity costs these may incur because of their attention being grabbed by the platform. Indeed, determining such opportunity costs may be quite difficult, if not impossible. However, factoring these costs in the analysis is essential if one needs to take into account all the social benefits and costs of the business model of digital platforms.

There are two possibilities to account for this opportunity costs of attention. A time-based model will focus on the percentage of time users spend online, from their available time excluding hours of sleep, and how much time from this is accounted for by Big Tech⁸⁹⁶. A money-based model would go try to assess the value of the attention time users spend on digital platforms. Evans notes the increasing amount of time users spend on Apps/Web accessed through smartphones and tablets or other multimedia devices, in comparison to the time they spent on other media, such as Live TV, DVR/Time-Shifted TV or AM/FM Radio etc.⁸⁹⁷. Evans only takes into account the time spent on ad-supported content, some of which is spent offline (e.g. newspapers, radio, TV). Then Evans relies on the economics of household production in order to measure the value of consumer attention. He divides the time people spent to three broad categories: labour, household production and entertainment/leisure time, acknowledging that this tripartite distinction does not account well for multi-tasking as people may do more than one type of activity at the same time. Evans recognises that 'consumers have a finite amount of time and must allocate it across competing uses'⁸⁹⁸. Indeed, for Evans, 'consumers allocate time to wage work until the marginal rate of substitution between consumption and leisure equals the marginal after-tax wage rate, which therefore provides a

896 See, for instance, E. Brynjolfsson & J Hee Oh, *The Attention Economy: Measuring the Value of Free Digital Services on the Internet*, Proceedings of the Thirty Third International Conference on Information Systems, Orlando, available at <https://aisel.aisnet.org/cgi/viewcontent.cgi?article=1045&context=icis2012>.

898 Ibid., 7.

monetary measure of the value of time⁸⁹⁹. From this starting point, he concludes that 'the opportunity cost of an extra hour consuming content is equal to the after-tax marginal wage rate'⁹⁰⁰. On this basis, Evans assesses the value of the 437 billion hours US consumers spend on ad-supported content to \$7,1 trillion (taking into account after-tax average wage as a measure of the opportunity cost of time), this figure coming down to \$5 trillion (if one takes into account before tax average wage rate) and \$2 trillion (if one considers after tax minimum wage)⁹⁰¹. This time is valuable and could of course be used for other things. Evans ventures that 'consumers receive surplus over and above what they pay in the form of time for consuming content'⁹⁰².

The content consuming users' time is not always produced by the digital platforms, their role being merely to match content with users grabbing their attention and then to resell users' attention in advertising markets, by matching an ad with a user who in all likelihood, in view of his past revealed preferences or inferences about his preferences, will be interested in it. Digital platforms therefore compete to get users to spend time with them.

The more a platform spends on content, the more attention it may get. However, the possibility of the platform to resell that attention is fixed as there is a fixed amount of time, or space, available for ads, as there is a risk that in case the platform includes more ads, this may have negative effects to the attention of the users which may abandon the platform, of course in case there are less-intensive in terms of ads platform available. Advertisers realise diminishing returns from the attention they attract through content as consumers have decreasing propensity to buy advertisers' products if they spend more time on the free content.

Evans' analysis does not take into account the fact that as it is observed in the EU panel of experts report, '(m)any consumers are typically not consciously participating in this exchange, or do not appreciate the value of the attention they are providing'⁹⁰³. Although he acknowledges that the HHI of the top 1000 websites, in terms of time share, has increased from 2868 in 2008 to 2968 in 2013, therefore showing that this is a concentrated market, he also notes that 'the HHI understates the degree of competition for attention because it is a static measure that does not reflect the entry and exit, and expansion and decline, of websites, which takes place over relatively short periods of time'⁹⁰⁴. For instance, he refers to studies that have found that the top five websites

accounted for 42.5% of the time in 2008 but their share declined to 20% by 2013⁹⁰⁵. However, the same study notes the limit of the number of websites that can be visited by households and that people do not split time into more numerous and shorter site visits⁹⁰⁶. This indicates that browsing behavior may be stable over time, thus limiting the opportunity of other websites to make serious gains in these attention markets. Indeed, if one looks to the share in terms of time spent on the top 20 websites in the UK, the market looks quite concentrated (see Figure 4.17).

Figure 4.17: Share of time spent on top 20 sites by UK users

Source: Comscore cited in Furman et al Report (2019), 29

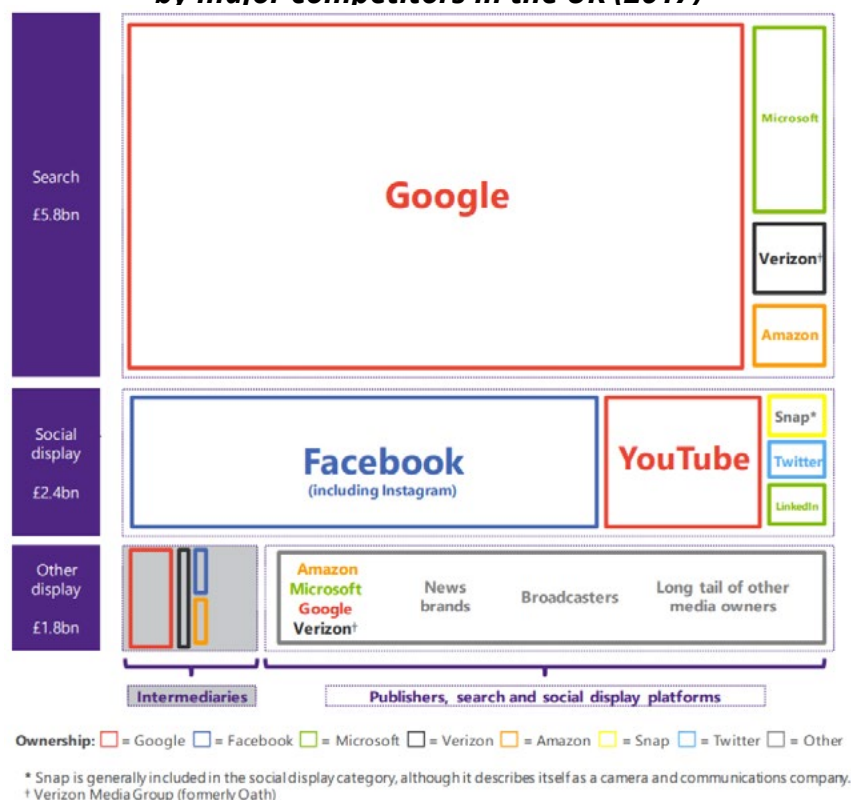

One may also note that other studies have found that the top websites' share in terms of advertising revenue indicates that the market of attention (taking into account its advertising side) is quite concentrated (see Figure 4.18.).

More generally, Evans takes the view that advertising fulfils the function to inform the consumers so as to enable them to make more efficient choices, and it is therefore

something that may be considered as contributing to consumer surplus⁹⁰⁷. By espousing this assumption Evans seems to adhere to the informative view of advertising, according to which the principal function of advertising is to convey information to consumers, and from that perspective, to help them choose the products/services that correspond the best to their preferences⁹⁰⁸. This view has been advanced by authors close to the Chicago School of economics⁹⁰⁹. Telser, a proponent of that view, argued that ‘advertising is frequently a means of entry and a sign of competition’, in view of its role as ‘an important source of information’ for consumers⁹¹⁰. More importantly, although Telser recognizes that ‘firms which have some monopoly power are more likely to advertise because they can obtain most of the increased sales stimulated by their advertising’, he also finds a weak correlation between concentration or stable market shares and advertising, thus questioning the causal link earlier made by the proponents of the persuasive view⁹¹¹. Nelson also advances an informative view argument by distinguishing between search goods (whose quality can be determined prior to purchase, even if at high costs) and experience goods (whose quality can only be determined after consumption) and observing the benefits of advertising (and enhanced product differentiation) for experience goods (through the provision of indirect information on the product)⁹¹². Advertising constitutes a way for the firms to signal to consumers that they are the most efficient (low-cost) firms, since they seek demand expansion (the ‘signalling-efficiency effect’ of advertising). Furthermore, ‘(a)dvertising increases the probability of a consumer’s remembering the name of a brand’, and therefore advertising assists the consumer by informing his choice (‘the match-products-to-buyers effect’). Hence, advertising, as well as any mechanism of product differentiation (such as branding) stimulate price comparisons and therefore price competition. Finally, advertising, and brands in general, assist the consumer to draw positive associations between specific products and quality, reminding them of their previous experience with the product (‘the repeat-business effect’)⁹¹³.

One may nevertheless take a more negative view on advertising as to its benefits for consumers, and adopt the persuasive view that focuses on the potential of advertising to manipulate consumers. Advertising may be perceived as a tool to alter consumer preferences and to create product differentiation and brand loyalty, driving the demand curve of the advertised product to become more inelastic and thus leading to higher prices for consumers, as well as have an ‘entry-deterrence effect’⁹¹⁴. Empirical work has

confirmed some of the intuitions of the 'persuasive view'. Comanor and Wilson performed a multi-variate regression analysis of the averaged profits of manufacturers in 41 consumer-good industries for a period of three years and found 'empirical support for the conclusion that the heavy volume of advertising expenditures in some industries serves as an important barrier to new competition in the markets served by these industries'⁹¹⁵. More recently, with regard to product differentiation Bronnenberg *et al* highlighted that brands, advertising, or other past experiences and social milieu, such as childhood, lead to 'preference capital', which could be a valuable asset for incumbent firms and a source of long-term economic rents for them⁹¹⁶. This explains, according to these authors, why consumers have high willingness to pay for particular brands, even when the alternatives are objectively similar⁹¹⁷. This evidence indicates that brand loyalty may not always be a natural outgrowth of consumer preferences and that there is value for firms to use advertising, branding or other forms of product differentiation in order to establish some form of 'preference capital'. This strategy may generate high willingness to pay for consumers and presumably steady economic rents for the incumbents in the future, without that being justified by the objective characteristics of their product/or service in comparison to the products/services of a new entrant. In other words, incumbent firms may have the incentives and the ability to alter the utility function of consumers in order to increase their profits.

The emphasis put on the potential of manipulation through advertising or more broadly choice architecture and agenda-setting may indeed shed light on one of the sources of power for digital platforms, and the reasons their valuation by financial markets has skyrocketed in recent years. The more people switch to a digital an 'always connected' way of life, the more the opportunities to influence their preferences through choice architecture or outright manipulation become more important. Firms may more actively manipulate the choice of consumers in digital markets⁹¹⁸, and will be able to do this even more effectively as the control of devices moved from screens, where the user benefits from a relatively open architecture, to voice-controlled devices. The message provided by advertisers may be even more convincing the more it is targeted to the specific vulnerabilities and core beliefs of the consumer. Hence, the value of digital platforms is not only related to their matching function but more importantly to their predictive and manipulative function. This raises interesting issues for competition law enforcement, and its interaction with other areas of law aimed to protect consumers from deception or manipulation, such as consumer law. The discussion over the effects of digital

platforms on attention markets also raises the potential of exploitation of consumers. This can take different forms related to the different activities of digital platforms. First, harvesting personal data may affect privacy and produce consumer harm, if privacy is considered as an important parameter of competition by consumers (see our analysis in Chapter 11). Second, by proceeding to frequent ‘attentional intrusions’ digital platforms may commit ‘attention theft’, defined as ‘the non-consensual seizure of the scarce resource of attention, yielding cognitive impairment’, thus producing consumer harm⁹¹⁹. Thirdly, digital technology offers the enhanced possibilities of personalisation, which may in turn lead to abuses, such as algorithmic discrimination and personalised pricing. We explore the implications of personalisation for determining the field of the competition law assessment in the next Section.

4.4.3. Personalised markets

It is increasingly acknowledged that data collection is fundamental to firms’ ability to compete in the future Internet of Things (‘IoT’), Internet of Services (‘IoS’) and/or Internet of Everything. The firms that have obtained access to the largest amounts of data will benefit from a competitive advantage.⁹²⁰ Data analytics connected to the use of software for predictive modelling, will also reinforce the competitive advantages of such firms, with this ultimately being crystallised in architectural advantage because of their control of ‘idiosyncratic rent-earning resources’ (i.e. in the form of superior algorithms) or, more generally, by their development of capabilities that cannot be imitated by competitors (because of increasing returns to scale).⁹²¹ With the advancement of the IoT and IoS and the possible emergence in the near future of the Internet of Everything, the amount of data that will be collected will increase immensely, including in industries that were not previously digital.

Much of this data will relate to the digital identity of the consumer and will enable companies to draw a pretty accurate individual preferences map for each of their clients. More than just being dominant in an ‘attention market’⁹²², firms may be able to practice behavioural pricing or personalised price discrimination, which comes tantamount to first degree price discrimination (or person-specific pricing). This is now possible in view of Big Data and algorithmic pricing as practiced in online commerce, as sellers charge different prices depending upon a buyers’ search history, or “digital shadow”⁹²³. Recent calls

919 T. Wu, Blind Spot: The Attention Economy and the Law (March 26, 2017). Antitrust Law Journal, forthcoming, available at SSRN: <https://ssrn.com/abstract=2941094>, 9.

920 There is a discussion regarding the definition of ‘data’: does it encompass syntactic information, semantic information, or both; and where should one draw the line in reference to protecting ‘data’?

921 M. Jacobides, S. Winter & S. Kassberger, “The Dynamics of Wealth, Profit, and Sustainable Advantage”, (2012) 33 Strategic Management Journal, 1386.

922 On this concept, see T. Wu, Blind Spot: The Attention Economy and the Law (March 26, 2017). Antitrust Law Journal, forthcoming, available at SSRN: <https://ssrn.com/abstract=2941094>; D.S. Evans, The Economics of Attention Markets, (October 31, 2017), available at SSRN: <https://ssrn.com/abstract=3044858>.

923 M. Gal, ‘Algorithmic-facilitated Coordination’, DAF/COMP/WD(2017) 26 (noting that “ (a)s more data is gathered about each consumer’s preferences, a personalized ‘digital profile’ can be created by algorithms, which calculates and updates

for intervention against “behavioural pricing” (or personalised price discrimination)⁹²⁴, which may be considered as a form of algorithmic discrimination, illustrate the broader societal concerns (if not only economic) that are raised with regard to the perceived manipulation of consumers by companies, something as old as advertising exists.⁹²⁵ In the era of “machine learning” and Artificial intelligence-assisted pricing the risks of “digital” consumer manipulation may admittedly increase at an industrial scale.⁹²⁶ Digital markets exacerbate the above risks, in view of the possibilities they offer of “a vast psychological audit, discovering and representing the desires of society”⁹²⁷ and of each individual separately, offering sophisticated evaluation methods that are closely linked to the direct observation of consumer preferences, but also more broadly of a whole range of preferences expressed in social, and private life, through the means of socio-metric analysis⁹²⁸. Big data enable us to observe, allegedly more accurately, the inner mental states of people and potentially influence the way these form their core preferences. Such manipulative potential and of course the possibility that this may occur at a larger scale, in view of the possibilities offered by algorithms, data analysis and artificial intelligence, is clearly motivating public authorities to action.

This may later feed in the companies’ commercial strategies that may, for instance, develop personalised pricing strategies, which may be considered a form of price discrimination.

Personalised pricing improves the ability to distinguish customers and may lead to first degree price discrimination, as well as third degree price discrimination, when it is possible for the firms to apply group pricing, discriminating between groups of consumers. Subjecting to price discrimination final users may enable the producer to capture the entire consumer surplus, generate unequal treatment of various individual consumers

each consumer’s elasticity of demand in real-time. This digital shadow can then be used by suppliers to increase their profits even further, if they can price-differentiate between the offers they make to different consumers”).

924 See, Autorité de la Concurrence & Bundeskartellamt, Competition Law and Big Data (May 10th, 2016), 21-22, noting that although the application of EU competition law to these practices may be debated, in Germany, the Federal Supreme Court found that the national provision against the abuse of a dominant position can include a consumer protection dimension as regards price discrimination, see German Federal Supreme Court (BGH), „Entega II”, KZR 5/10, judgment of 07.12.2010. 928 Ibid.

or groups of consumers, and affect competition with other producers (not necessarily of the same relevant market), in the sense that by enabling the producer to charge a specific consumer as high as his willingness to pay, reduces the available income of the consumer to make other purchases. Different producers compete for the limited resources/budget of a consumer or a group of consumers.

Personalised pricing or “price targeting” has been observed in various markets.⁹²⁹ To the extent that this manipulation may result in welfare losses for individuals, or group of consumers, in the sense that the specific individual, or the specific group of consumers, could find its/their situation worse off, in comparison to a counterfactual where no such digital manipulation would have taken place, it can be argued that these deviations from the counterfactual situation need to be corrected through State intervention, eventually by competition law enforcement. But this is a matter for debate. One may argue that personalised pricing should not be considered as a form of “manipulation”, but as a technological opportunity to charge each consumer as much as her/his willingness to pay is. This may, for instance, enable some consumers that would not have been able to purchase the specific product, if a uniform price would have been implemented and would have been higher than their willingness, to pay for the product. “Personalised pricing” may have ambiguous welfare effects, depending on market structure and the trade off between the market “appropriation” effect to consumer with high willingness to pay versus the “market expansion” effect to consumers with a low willingness to pay of targeted pricing.⁹³⁰

Competition law intervention may also be motivated by fairness considerations (value ethics), in particular if personalised pricing is not transparent and thus consumers are not informed, or the need to limit an extensive use by the firms practising algorithmic discrimination of consumers’ sensitive personal data, in view of the purpose limitation and data minimisation requirements in the Data Protection regulation⁹³¹. These practices may also raise more conventional competition law concerns, as they discourage consumer search by making it harder or more expensive to return to buy after a search for alternatives, with the effect that the matching of products to consumers is sub-optimal and that consumers, on aggregate, may finish paying higher prices.⁹³²

929 See the analysis and examples provided in M Bourreau et al., *Big Data and Competition Policy: Market Power, personalised pricing and advertising*, CERRE Project Report (February 2017), 40-41 and the empirical studies they refer to.

930 For a discussion, see OFT1488, *The economics of online personalised pricing* (May 2013), available at http://webarchive.nationalarchives.gov.uk/20140402142426/http://www.of.gov.uk/shared_of/research/of1488.pdf ; M Bourreau et al., *Big Data and Competition Policy: Market Power, personalised pricing and advertising*, CERRE Project Report (February 2017), 43-45.

931 Art. 5(1) of Regulation (EU) 2016/679 of the European Parliament and of the Council of 27 April 2016 on the protection of natural persons with regard to the processing of personal data and on the free movement of such data, and repealing Directive 95/46/EC (General Data Protection Regulation – GDPR), [2016] L 119/1. See also Art. 9(1) GDPR and Section 2 of the Data Protection Act 1998 which require the data controller when processing personal data to obtain a specific and explicit consent to process these categories of data.

932 M Armstrong & J Zhou, ‘Search Deterrence’ (2016) 83 *Review of Economic Studies* 26

One may argue that the principle of ‘open market economy’ would require that economic value should be set in the context of a competitive process taking place on a market, where various actors, consumers and suppliers interact through the signals of price. Hence, charging a consumer a personalised price that would correspond to her/his willingness to pay, without him being aware of this and without enabling the specific consumer to benefit from the competitive process taking place at the ‘open market’ and the source of information this may provide so as to enable informed comparison with regard to the situation of other consumers. This is particularly important as one may argue that consumers value the competitive process as such, and not just the fact that the price of a product is within the range of their willingness to pay, which is also something that cannot be set in advance, but essentially cultivated in the context of a market involving continuous interactions between buyers and sellers. That said, it is important to explore if competition law is the best legal instrument to deal with welfare-reducing targeted pricing, or if other alternatives, such as consumer protection law, data protection and privacy rules, anti-discrimination law, unfair commercial practices law, regulation, may prove to be more appropriate, following a detailed comparative institutional analysis.⁹³³

Moving beyond personalised pricing, another implication of personalisation is that firms will be able to develop bespoke products that suit the individual preferences of their consumers without incurring prohibitive costs as they will be able to achieve economies of scale by developing various series of products that could satisfy the entire demand function of the specific consumer in various product categories. In this era of ‘mass personalisation’,⁹³⁴ these new conglomerates will not just control markets in the traditional sense but they will control the personalised markets of individual consumers on whom they hold a superior level of data than other firms. This, in turn, will enable them to cater for the entirety of demands and needs of that individual, for instance, in consumer goods or entertainment. Once a specific amount of data is harvested, these personalised markets will tip with the result that only one firm will have the capabilities to perfectly satisfy the individual consumer’s demand in an array of products. Indeed, consumers will economise their time if they rely on the personalised made-to-order and customised-to-their-preferences offer of one digital platform or reseller that has

933 See, M Bourreau et al., *Big Data and Competition Policy: Market Power, personalised pricing and advertising*, CERRE Project Report (February 2017), 45-47, noting restrictions on personalised pricing from data protection rules (the need to have the explicit consent of the data subject involved), consumer protection rules (disclosure to consumers about the prices and how they are calculated), unfair commercial practices (prohibiting in certain circumstances consumer profiling and considering this as a misleading commercial practice), free movement law (the Services’ directive prohibitions to discrimination based on the service recipient’s nationality or residence), as well as specific regulations on geo-blocking (see Proposal for a Regulation of the European Parliament and of the Council on addressing geo-blocking and other forms of discrimination based on customers’ nationality, place of residence or place of establishment within the internal market and amending Regulation (EC) No 2006/2004 and Directive 2009/22/EC, COM(2016) 289 final), or the application of competition law provisions against geo-blocking (see Chapter 2.3.3.3).

934 See, for instance, Deloitte, *Study on emerging issues of data ownership, interoperability, (re-)usability and access to data, and liability*, A study prepared for the European Commission DG Communications Networks, Content & Technology (2016); Industry 4.0, Study for the ITRE committee, European Parliament, (2016).

been able to harvest their personal data and, from that, gain a greater understanding of their individual preferences map. Firms may then be able to organise the production process within their ecosystem. They may do this by limiting access to an individual consumer's profile to a number of firms that they control, either directly or indirectly, and such access will be dependent on this latter firm ensures their products fit the relevant consumer's specific preferences. Even if one assumes that consumer preferences may evolve and that some degree of competition may still be possible, it is clear that mass personalisation will increase demand stickiness and the ability of firms to exploit consumers whilst simultaneously reducing consumer surplus, product variety and consumer choice.

Some of these 'personalised markets' may well appear in the pharmaceutical industry through the development of personalised healthcare, precision medicine and smart healthcare. Changes brought about by developments in digital technology will transform the pharmaceutical and the medical services industries. Data and algorithms are important game-changers as they will enable the development of new 'beyond-the-pills' solutions. Firms will be able to combine drugs, sensors collecting information on the patient's condition and different sorts of data (early R&D data, digital medical records, including diagnostic results, medication history, genomic or gene-expression data, lifestyle data) to develop such solutions. Future medical service providers may be able to 'personalise' patient care, better identify optimal therapies, better predict the patient's response to treatment, as well as engage more fully with physicians, in particular, enabling them to draw from superior insights when making decisions.

The digital revolution will likely transform the pharmaceutical and health service industries beyond recognition in the same way the media, retail, transport and banking industries have been reshaped in recent years. The role of 'personal data', in particular 'genetic data' (such as gene expression data) and 'lifestyle data', in the delivery of personalised medical services and personalised medicine will change the current paradigm, which is very much based on the development of therapies that target an entire population. New digital and/or data-based business models will certainly develop on the basis of competitive advantage in accessing this pool of personal data. This, in turn, will enable the development of health and medical solutions tailored to the characteristics of a specific individual. Hence, it might be expected that the main industrial actors in this area in the future will not only be the pharmaceutical industry and biotechnology companies but also digital intermediaries, which may rely on their superior technological (e.g. algorithms, specialised human resources etc.) and data-gathering capabilities in order to move to the centre of this new emerging health services ecosystem. This move may be based on their own initiative or be done in combination with other firms benefitting from expertise in a specific domain.

In view of the 'intermediation power' some digital platforms may enjoy, to the extent that intermediaries dispose of privileged access to consumer data and/or of 'a significant ability' to steer consumers,⁹³⁵ such platforms may acquire a unique level of access

935 H. Schweitzer, J. Haucap, W. Kerber and R. Welker, "Modernising the Law on Abuse of Market Power", (2017) Report for

to and control over personalised data. This raises concerns over them being the sole source and controller of it in relation to further processes of data monetisation and commercialisation; or of multiple firms being the individual controllers over different sources of data, thus constituting 'data thickets'. The right of access to the data (i.e. through a request to the manufacturer, maker or generator of the data) will certainly constitute an important element in devising the public policy aim that should frame the principles that would apply in each regulatory framework. However, conceiving access to data as a right that any actual (and/or potential) business participant may stumble across raises considerable theoretical and practical difficulties, such as the issues of:

- ownership of this data (i.e. if data may be 'owned'),
- the business practices of firms holding the data limiting or conditioning access to it (i.e. hold-up situations in cases of split ownership),
- this information is subject to moral rights,
- this information is subject to rules concerning inalienability,
- regulatory prohibitions or limits to the sharing of personal data,⁹³⁶ and
- the technical means and way in which access to the specific data will be implemented and the transaction costs inherent in such (these costs are likely to be considerable).

the (German) Federal Ministry for Economic Affairs and Energy. For example, the German Competition Act was amended in 2017; it states that "access to relevant data is a potential source of market power". See also W. Kerber, "Digital Markets, Data, and Privacy: Competition Law, Consumer Law and Data Protection", (2016) *Gewerblicher Rechtsschutz und Urheberrecht Internationaler Teil*, 639-647. There are several authors who purport that holding big data does not equate to market power: G. Colangelo and M. Maggolino, "Big Data as Misleading Facilities", (2017) *Bocconi Legal Studies Research Paper No. 2978465*. Generally, they argue that big data does not create a significant barrier to entry and they base their claims, inter alia, on the non-exclusive and non-rivalrous nature of data and a claimed ease of collecting it, while disregarding many potential entry barriers. Other scholars argue that the harm created by big data pertains mainly to privacy. Yet, these conclusions are based on the limited existing economic studies on big data, which often focus on one specific market (most commonly on search engines or personal data markets). See, for example, Rubinfeld and Gal, (41), 339; D. Tucker and H. Wellford, "Big Mistakes Regarding Big Data", (2014) 6 *Antitrust Source*, 10; M. Ohlhausen and A. Okuliar, "Competition, Consumer Protection, And the Right [Approach] To Privacy", (2015) 80 *Antitrust Law Journal*, 121; J. Cooper, "Privacy and Antitrust: Underpants Gnomes, the First Amendment and Subjectivity", (2013) 20 *George Mason Law Review*, 1129.

936 This is particularly the case for "genetic data", which forms a "special category" under Article 9 of the GDPR. According to Recital 34 of the GDPR, "genetic data should be defined as personal data relating to the inherited or acquired genetic characteristics of a natural person which result from the analysis of a biological sample from the natural person in question, in particular chromosomal, deoxyribonucleic acid (DNA) or ribonucleic acid (RNA) analysis, or from the analysis of another element enabling equivalent information to be obtained". However, this is not the only type of personal data of interest. There is also ample discussion on the issue of the ownership of databases containing such type of data, in particular if this is generated by sensors or machines/algorithms for the purposes of the 'Database Directive' 96/9/EC (i.e. Directive 96/9/EC of the European Parliament and of the Council of 11 March 1996 on the legal protection of databases, [1996] OJ L 77/20) in view of Article 1(3) of the Directive, which provides that "protection under this Directive shall not apply to computer programs used in the making or operation of databases accessible by electronic means". For a discussion, see Joint Institute for Innovation Policy and Technopolis Group, "Study in Support of the Evaluation of Directive 96/9/EC on the Legal Protection of Databases", (2018) Study for the European Commission DG Communications Networks, Content and Technology.

One should expect that many of the actors operating in the digital pharmaceutical and health services industry will engage in extensive long-term collaborations in reference to the creation, the exchange and trade of data. These collaborations will likely be based on the high level of transaction costs and specificity of data and technological capabilities required by this industry in order for it to flourish. It should also be expected that various industry players will seek to control bottlenecks and, thus, preserve their ability to gain abnormal profits, even after the superior technological capabilities of which they currently dispose have dissipated in view of the diffusion of any necessary and relevant technologies among all players in this new ecosystem.

Indeed, pharmaceutical firms, especially the so-called 'Big Pharma' ones, have traditionally focused on "taking drugs to the market" whilst having, as the basis for their business model, a large patent portfolio consisting of substance and/or process patents. They have traditionally been at the forefront of controlling and driving the (downstream) procedure of obtaining marketing authorisations whilst also managing the (upstream) R&D procedure by purchasing or licensing-in potential successful R&D results from often smaller R&D firms. Now health data and the control of health data will challenge that traditional value chain of taking drugs to the market.

Effectively, the digital transformation has caused both a need and opportunity for pharmaceutical firms to explore new business models, i.e. the logic or framework they use to create and capture value.⁹³⁷ Business model innovation can be particularly challenging in the context of disruptive change especially when there is a lack of clarity as to what the new business model would or should look like,⁹³⁸ and its organisational structure.⁹³⁹ Moreover, the complexity involved in emerging technologies, in terms of both potential problems and solutions, gives rise to a need to connect disciplines and organisations. This will likely lead to more open business models⁹⁴⁰ focusing on joint value creation with complementary partners operating within larger ecosystems.

Future product markets will likely face a paradigm shift when data becomes the starting point of the value chain as pharmaceutical products and medical services will likely be framed according to the genetic and lifestyle data of an individual patient. The vast amounts of collected data will also enable producers to understand what consumers and/or patients value in the pharmaceutical products and medical services they purchase. This will influence the way in which products are designed and developed thereby increasing product quality, which, in turn, should help generate products that, in accordance with preferences revealed by their data, match the relevant buyer's expectations. This could fundamentally alter 'old economy' markets. They would no longer be solely focused on marginal cost and price. Instead, firms would compete on a wider range of

variables. The knock-on effect of the possible personalisation of offers and the dependency of patients on one specific firm, may provide said firm with further sources of monopolistic rents thereby reducing the percentage of the surplus going to consumers.

Health data could, for example, enable the creation of new human health services solutions. The organisation of health services and the production of pharmaceutical products within the same digital eco-system would allow for feedback loops feeding health information back to pharmaceutical companies. These companies would then be able to develop business processes that could respond in real-time in order to improve the effectiveness of the relevant drugs or medicinal products. Such improvements would not be done on the general level of populations but on the specific level of individual patients. Patients would also be given the possibility of becoming more engaged with their health through an array of digital tools that provide them with the possibility of being better informed about their health and making lifestyle changes accordingly and of monitoring their own health and constantly sharing this information with medical experts. Data would become part of a “digital ecosystem that constantly monitors a patient’s condition and provides feedback to the patient and other stakeholders”,⁹⁴¹ and tailors any treatment or therapy required to the patient’s clinical and lifestyle needs.

In the health sector, several firms (claimed ‘proprietors’) hold different types of data. For, example, we have clinical (i.e. patient) data, which is normally held by physicians, and we have clinical trial data held by pharmaceutical firms. Pharmaceutical firms also hold early R&D data. We have public health authorities, insurance firms and specific health data firms (e.g. IMS Health), which hold data regarding the cost and consumption of pharmaceuticals. Further, we have Internet firms like Google, or specific vertical medical search engines, may hold much data about patients’ behaviour, their fears and conduct. If the data collected by these bodies could be anonymised, pooled and combined, that might prove very useful in the fight against all kind of diseases. It may substantially decrease the time currently required for identifying outbreaks of diseases, for developing new drugs or health solutions, for understanding the impact of new drugs, side-effects etc.⁹⁴² Personal health solutions can thus be developed. Indeed, data pools may be very successful in the human medical products and healthcare industry.

Generally, the current situation on data-driven markets is that there are a number of *de facto* data holders, each with a limited set of data. This situation has the potential to lead to market failure because to achieve the best results from any analysis undertaken, either all the relevant firms would need access to all this data or there would need to be one sole firm/provider that would be responsible for such. This is where the need for a federated ‘data commons’ becomes clear; it is necessary to enable interoperability between the various systems put in place by the participants in this ecosystem so that they provide an effective solution for patients. Borrowing the concept of ‘integrated

care' from health law,⁹⁴³ the importance of ensuring that data is shared and relied upon so that care becomes responsive to the specific person's needs and genetic characteristics is crucial. Investigations should be undertaken to see whether dynamic efficiencies of 'data aggregation' exist in specific sectors and whether the market is capable of dealing with such. Investigations should also be undertaken to consider whether a federated data commons may be organised in the context of 'data pooling' or organised and closely-supervised in the context of markets for 'data trading' (see our analysis in the context of the IoT in Chapter 10)⁹⁴⁴.

4.4.4. Ecosystems

The shift from competition and value capture to mixed strategies of value capture and value creation, involving strategies of co-opetition, indicates that an additional 'field' of competition-related activity should also be added: that of the 'eco-system'.

Developed in the early 1990s,⁹⁴⁵ the concept of an 'ecosystem' has been defined in broad terms as 'a group of interacting firms that depend on each other's activities'.⁹⁴⁶ Teece notes that a characteristic of eco-systems is their 'co-evolution' in the sense that the 'attributes of two or more organisations become more closely complementary', 'the system being typically reliant on the technological leadership of one or two firms that provide a platform around which other system members, providing inputs and complementary goods, align their investments and strategies'. Teece also notes that 'co-creation' is a characteristic of eco-systems as two or more organisations 'combine forces to pioneer new markets'.⁹⁴⁷ Adner observes that 'the ecosystem is defined by the alignment structure of the multilateral set of partners that need to interact in order for a focal value proposition to materialise'. Adner proceeds to define this 'alignment structure' as 'the extent to which there is mutual agreement among the members regarding positions and flows'.⁹⁴⁸ The concept of 'eco-system' has emerged as the dominant idea for depicting the competitive environment in the modern digital economy. The 'eco-system manager' determines the elements of the value chain that will need to be internalised and those which will be supported externally so as to capture value. Most studies on eco-systems focus on the role of the eco-system as a 'hub' of inter-firm relations taking place within the context of a platform, often referred to as the 'lead firm' or 'ecosystem

captain', which 'defines the hierarchical differentiation of members' roles and establishes standards and interfaces, a number of formal mechanisms, such as the management of standards and interfaces, platform governance, IP rights etc. forming the 'key tools that hubs use to discipline and motivate ecosystem members'.⁹⁴⁹ However, from a theoretical perspective, a platform eco-system has never been the only option even if, in practical terms, the platform model has become dominant – it is possible to imagine an eco-system in which power is neither concentrated in a hub nor governed by a platform but is distributed among various economic actors and stakeholders who will take decisions by consensus. This model of governance is more frequently associated with blockchain technology.

The essence of this new insight on ecosystems comes from the realisation that competition analysis should engage with the 'value capture' strategies put in place by economic actors competing for strategic or architectural advantage.⁹⁵⁰ These should form the starting point of competition analysis, rather than the relevant market concept which no longer constitutes the sole reference point firms consider when devising their strategies and identifying the competitive constraints to which they are subject. Abandoning solely focusing on the relevant market concept also stems from the relatively more limited role of price competition in the digital economy. Firms often compete for customers in order to (i) enlarge their customer base, and/or (ii) take advantage of network effects and be perceived by financial markets as holding a 'bottleneck', even if such trade, from a price-cost perspective, may not be profitable. This struggle for a large customer base explains why firms continue to offer 'free goods', even if the gains in market share they obtain or their ability to harvest consumer data (personal data being the 'price' to pay for these 'free goods') may not be immediately monetised in data markets. However, capturing a large customer base at reduced or negative profitability is not the ultimate aim of these strategies. This strategy makes sense if, by acquiring a large customer base, firms are able to develop dynamic capabilities in prediction (for instance, the firm may use consumer data to enable it to improve its algorithms), which is of essence in today's 'surveillance capitalism'⁹⁵¹. These benefits do not only materialise in the long-term but may also be enjoyed through a higher market valuation by the financial markets in the short-term.

4.4.5. The behavioural dimension: Market failures at the demand side

The assessment of consumer welfare in competition law relies only on observable behaviour, the 'revealed preferences' of consumers, which are amenable to empirical verification or refutation⁹⁵². The aim is to ascertain an individual's preferences by observing that individual's market behaviour. Assuming, under the consistency principle, a single

952 P.A. Samuelson, A note on the pure theory of consumer's behaviour, (1938) 5(17) *Economica*, New Series, 61, 63.

observed choice reveals a stable preference, one could infer the preferences of consumers from the economic choices they make. The welfare analysis in competition law works within a revealed preferences paradigm, when relevant and reliable data on actual purchases are available. The use of quantitative methods (econometrics) enables in this case competition authorities to estimate the elasticities of demand, in particular the cross-price elasticity of demand, which measures the sensitivity of demand for one category of products to the price of another category. However, such data is not often available or not specific enough to estimate the cross-price elasticities of demand for the product(s) in question, in which case properly designed survey methods will measure preferences over hypothetical products and alternatives. In this case, the preferences will be *stated*, as opposed to revealed preferences. The survey method will aim to create a controlled experiment, testing the reaction of consumers to a set of choices that includes the specific product at a low price and another set which includes the same product at a higher price. These discrete methods of surveying choice attempt to mimic the situation of choice faced by the consumer in the real-world, but is a proxy for revealed preferences, assuming that the survey is well designed, the process was conducted so as to assure objectivity, and that a representative sample of consumers to be surveyed has been selected. The approach relies on an axiomatic analysis of preferences.

Behavioural economics has challenged the link between preferences (revealed or stated) and welfare, which forms the basis for the welfare analysis performed in competition law. It cannot be assumed that consumers' choice on the market represents their "true preferences". However, there are at least two caveats with this approach.

First, it does not describe accurately the behaviour of consumers. Research by Kahneman and Tversky showed that human behaviour may be described as the outcome of two different cognitive systems/processes of choice, which inhabit every individual⁹⁵³. In what was called System 1, the individual operates automatically and quickly, with little or no effort and no sense of voluntary control. Decisions are reached through intuition, emotional and affective elements playing an important role in decision-making, which relies on heuristics, thus reducing 'the complex tasks of assessing probabilities and predicting values to simpler judgmental operations'⁹⁵⁴. In System 2, the individual allocates attention to effortful mental activities, including complex computations. System 2 is mobilised when a question arises for which System 1 does not offer an answer or when an event is detected that violates the model of the world that System 1 maintains. The division of labour between System 1 and System 2 is highly efficient as it minimizes effort and optimizes performance. Processing power biases of individuals may push them to a choice overload, where the multiplication of the options offered to consumers may lead to sub-optimal choice⁹⁵⁵, in the sense that consumers may follow rules of thumbs,

953 D. Kahneman, *Thinking, fast and slow* (Allen Lane, 2011).

954 A. Tversky and D. Kahneman, *Judgment under Uncertainty: Heuristics and Biases*, (1974), *Science*, New Series, Vol. 185, No. 4157, 1124.

955 This is the classic problem of "confusopoly". See, P. Diamond, *A Model of Price Adjustment*, 3(2) *J. Econ. Theory* 156 (1971) [if all firms set the same price (monopoly price) no consumer finds it worthwhile to incur the search cost to find the best deal; and if no consumer is informed, then each firm will set the monopoly price to exploit those consumers

for instance imitating what other consumers do rather than make their own decisions, in order to satisfy their preferences. Richard Thaler, one of the main representatives of the behavioural economics movement, makes this clear when he uses the term “quasi-rationality” to denote behaviour that is situated between full rationality and purely irrational behaviour, when people try to behave as if they were fully rational, but they are nonetheless subject to systematic error⁹⁵⁶.

Tversky and Kahneman advanced a theory explaining decision-making under conditions of risk. They argued that most people violate all the axioms of expected utility theory. Their prospect theory is based on psychophysical models and presents a different account, and a more accurate prediction, of how people really behave⁹⁵⁷. They found that people’s attitudes toward risks concerning gains may be quite different from their attitudes toward risks concerning losses. Loss aversion and endowment effect imply that selling prices should be higher than buying prices as the minimal compensation people demand to give up a good is often several times larger than the maximum amount they are willing to pay for a commensurate entitlement⁹⁵⁸. They distinguished between different phases of decision-making. During the *editing/framing phase of decision making*, they observed the influence of framing effects, as choosing an option may be affected by the order or manner in which it is presented to a decision maker and choice can be affected by trivial manipulations in the construction of available options. During the *evaluation phase* in decision-making, the *status quo* serves as an operative reference point and hence has a value function, while a different function, the *weighing* function, measures the impact of the probability of an event on the desirability of a prospect. They advanced the idea that this psycho-scientific framework should be adopted as a basis for investigating individual (economic) behaviour.

Second, the current approach ignores the way preferences were formed at the first place. Research on the foundations of human sociality has found that preferences are not exogenous but that they are shaped by the economic and social interactions of everyday life, thus questioning the foundations of marginal and ordinal theory, which take preferences as a given and a fixed norm that influences decision-making⁹⁵⁹.

who randomly come to it (Diamond’s paradox)]; R. Spiegler, Competition Over Agents with Boundedly Rational Expectations, (2006) 1(2) Theoretical Econ. 207; B. I. 957 D. Kahneman and A. Tversky, Prospect Theory: An Analysis of Decision under Risk, (1979) 47(2) Econometrica, 263.

958 The loss aversion biases include endowment biases (consumers value something more once they have owned it more than before they own it).

959 J. Henrich, R. Boyd, S. Bowles, C. Camerer, E. Fehr, & H. Gintis, Foundations of Human Sociality: Economic Experiments and Ethnographic Evidence from Fifteen Small-Scale Societies p. 46, noting that “the institutions that define feasible actions may also alter beliefs about consequences of actions and the evaluation of these consequences. For example, a market-oriented society may develop distinct cognitive capacities and habits. The fact that almost everything has a price in market-oriented societies provides a cognitive simplification not available to people in societies where money

This has important implications on the way we conceptualise consumer behaviour in competition law. Thaler suggested that neoclassical price theory of consumer behaviour, which was based on a rational maximizing model describing both how consumers should choose, but also how they do choose, may make systematic errors in predicting behaviour as consumers act in a manner that is inconsistent with the theory. He gave the example of individuals underweighing opportunity costs, or failing to ignore sunk costs (costs they would not be able to recover), as well as their complex search behaviour⁹⁶⁰. From a legal perspective, the quasi-rationality framework and the new positive theory of consumer behaviour proposed by Thaler has far-reaching implications, as it identifies a new form of “market failure”, this time not due to externalities, which identify imperfections of the price system because of a divergence between private (to the parties of a transaction) and public benefits and costs, but due to internalities, that is situations in which people do not internalise all consequences of their actions on themselves because of bounded rationality⁹⁶¹.

Limits in the cognitive capacities of consumers lead them to boundedly rational choices, or as economist Dan Ariely puts it, they act as “predictably irrational”⁹⁶². People tend to make judgments about the likelihood of an event, on the basis of how easily this event comes to mind (the availability heuristic), hence, indicating that prior exposure to a number of events may influence an individual’s subsequent judgments⁹⁶³. Similarity of an event or product may also serve as a cognitive shortcut in decision-making, which explains, for instance, why the package of a generic (store) brand (private label) looks similar to that of an established national brand in order to influence consumers’ choice (the representativeness heuristic)⁹⁶⁴. Ariely advances the concept of “zero-price effect”, which suggests that the usual cost-benefit analysis cannot account for the psychological effect of a free good, consumers perceiving it as intrinsically more valuable than a reduction of the price of the same product from £0,15 to £ 0,01, because of the “affect heuristic” associating free goods with a good feeling, which surfaces automatically when making decisions under System 1⁹⁶⁵. Decisions in risky or uncertain situations

plays a lesser role: namely, allowing the aggregation of disparate objects using a monetary standard as in ‘\$50 of groceries’. To take another example, extensive market interactions may accustom individuals to the idea that interactions with strangers may be mutually beneficial. By contrast, those who do not customarily deal with strangers in mutually advantageous ways may be more likely to treat anonymous interactions as hostile or threatening, or as occasions for the opportunistic pursuit of self-interest”.

are often influenced by anticipatory feelings and emotions experienced in the moment of decision-making⁹⁶⁶. Humans are also averse to change and exhibit a status quo bias, the formation of a habit making it difficult to disengage, unless the incentive to do so is strong. However, this may indicate that higher prices may not be enough for consumers' to switch their existing suppliers, procrastination and inertia eventually limiting their ability to exercise an active choice⁹⁶⁷. Of particular interest is also the fact that human beings often attach more importance to present events than future events, discounting future benefits for actual benefits. Thus discounting is non-linear and its rate may vary over time. Time inconsistency bias may also manifest itself by the impossibility to predict accurately our preferences in the future⁹⁶⁸. Preferences are context-dependent, the framing of the choice exercising an important influence over the decision of consumers⁹⁶⁹.

Hence, consumers do not make decisions in isolation, in order to satisfy their given preferences, but are also embedded in social environments, which inevitably influence, one might even say construct their preferences⁹⁷⁰. Because of these broader social preferences that often frame individual ones, people show that they prefer fairness and reciprocity over inequality and pursuing one's own self-interest⁹⁷¹. It is not only monetary incentives that count, but also people's perception of self, in other words, their social identity⁹⁷². Preferences are influenced by social roles, and more broadly social norms, which vary across cultures and contexts. Preferences may even follow choice, instead of guiding it, the order of preferences aiming mainly to rationalize/justify actions after the fact.

It was reported in several markets that behavioural biases may limit consumers' ability to switch to the best supplier⁹⁷³. Similar issues may also arise in digital markets, where the choice of the consumers is any case subject to the choice architecture of their smart-phone screen, thus raising the risk of manipulation. Choice architecture may even be

966 The risk as feelings model of decision-making: G. Loewenstein, *Emotions in economic theory and economic behaviour*, (2000) 90(2) *The American Economic Review* 426G. Loewenstein, E.U. Weber, C.K. Hsee, N. Welch, *Risk as feelings*, (2001) 127(2) *Psychological Bulletin* 267.

Pap.* 647; In a subsequent report the OFGEM noted that two third of consumers' energy accounts are with one of their ex-monopoly electricity suppliers, which provides evidence of a status quo bias and time inconsistency: *Ofgem Discussion Paper: What can behavioural economics say about GB energy consumers?*, March 2011, available at http://www.ofgem.gov.uk/Markets/RetMkts/rmr/Documents1/Behavioural_Economics_GBenergy.pdf.

more tightly controlled in the future in the context of voice technology, to the extent that there is a higher risk of ‘manipulation’ and reinforcing consumer bias in the context of a voice-based recommendation than when the user is at least offered the possibility to choose among various options on a smartphone’s or tablet’s screen⁹⁷⁴, although this risk has not materialised yet as voice assistants are presently used for simple operations⁹⁷⁵.

The manipulative dimension of targeted advertising practised by digital platforms also hints to a process of value generation and capture in the digital era that is in many respects different from that of industrial capitalism. As Zuboff explains, the ‘invention of targeted advertising paved the way to financial success, but it also laid the cornerstone of a more far-reaching development: the discovery and elaboration of surveillance capitalism’⁹⁷⁶. Data are of course the raw material that are necessary for ‘surveillance capitalism’s novel manufacturing processes’. During the initial stage of the development of digital capitalism, digital platforms, collect behavioural data tracking the behaviour of users, which, with the help of analytics leads to improvements in the services provided by the platforms, which compete with each other in order to take advantage of network effects and manage to tip the market in their favour. In this intense competitive struggle platforms compete in order to gain the highest possible market share, if need be by luring users providing them services at zero or even positive prices and rewards. This often explains why the digital platforms in this initial stage not only do not make profits but have suffered significant losses and have been dependent on the support of financial investors. The latter were attracted by the prospects of the digital platform to emerge as the winner if this competitive struggle for the market. This is of course part of the story, as at the same time the digital platforms participate to the ‘winner takes most’ competition in these ‘zero-priced’ markets, they are harvesting a considerable amount of data, not always with the aim to recycle this for the benefit of their users with service improvements, but with the aim to constitute what Zuboff calls ‘behavioral surplus’⁹⁷⁷. This is often camouflaged as ‘digital exhaust’ or ‘digital breadcrumbs’, presented as the equivalent of industrial waste and the necessary leftover from the production process, that for efficiency purposes should not be left into the ‘atmosphere’ but captured in order to be recycled in ‘useful data’. All content becomes a source of this behavioural surplus: the behaviour of people tracked, ‘their patterns of connection, communication, and mobility, their thoughts and feelings, and the meta-data expressed in their emoticons, exclamation points, lists, contractions, and salutations’⁹⁷⁸. Computer mediation is thus repurposed on ‘extraction architecture’, where a number of devices, fixed, portable and wearable technology, soon to become invisible through nanotechnology and bio-hacking.

The industrial waste metaphor does not adequately portray the real purpose of harvesting this data, which is driven by a 'full-blown logic of accumulation'. This logic takes different forms. First, it serves the construction of a dynamic online advertising marketplace, where digital platforms auction to advertisers, not the attention of the users as such, as these are still free not to click through the ad, but 'derivatives of behavioral surplus' on the basis of behavioral predictions made by Google as to the likelihood that a specific user will click through the ad and proceed to a purchase⁹⁷⁹. As Zuboff explains 'users were no longer ends in themselves but rather became the means to other' ends⁹⁸⁰. Digital platforms share these 'surveillance assets' with the partners in their ecosystems, or commercialise them in order to gather 'surveillance revenues' that are then accumulated in 'surveillance capital'⁹⁸¹. However, 'advertising is 'the beginning of the surveillance project, not the end'⁹⁸². The data is, indeed, used in order to develop the digital platforms' evolving AI capabilities. These enable them to make better predictions about the individuals' future behavior and to develop specific prediction products which are offered into new kind of markets trading exclusively in future behavior. As Zuboff explains '(s)urveillance capitalism's profits derive primarily from these 'behavioral futures markets'⁹⁸³. In this surveillance capitalism era, monopolies and bottlenecks are not constituted with the aim to raise prices, as traditional neoclassical theory assumes, but in order to 'corner' 'user-derived raw material supplies' and protect 'critical supply routes for the unregulated commodity that is behavioural surplus'⁹⁸⁴. Competitive struggles are not just for market shares in delimited markets, but for dominance of the dispossession cycle and the generation of behavioural surplus that will itself be highly valued in behavioural futures markets. This 'dispossession cycle' relies on incursion practices into 'undefended spaces' (a laptop, an email to a friend, a web page, the street you live), undefended because of the expectations that these will be unobservable to a third party and therefore out of the commodification and market logic, in order to 'kidnap' behavioural surplus⁹⁸⁵. It then develops because of an 'habituation' process, in which, these practices of incursion become normal and are 'rapidly bolstered by growing ecosystems of stakeholders'⁹⁸⁶. Should social tensions arise, digital platforms adapt and redirect the practices in larger projects of surveillance, for instance the Google maps project evolving to a more spectacular project of incursion with the development of the self-driving car or Google cities⁹⁸⁷. The surveillance capitalists omnipresence and superior capabilities to predict will turn them to 'copilots' of our lives, predicting where and when a person might spend time, and making the adequate recommendations, or

trading these behavioural futures in real time⁹⁸⁸. The market frontier is pushed to the extreme, all predictable behaviour becoming a source of behavioural surplus. In this world, 'unpredictable behaviour is the equivalent of lost revenue'⁹⁸⁹.

These 'behavioral futures markets' will be personalized, to the extent that more than just personal data, the surveillance capitalists will trade 'human consciousness' that will be the next territory of commodification, after that of land, labour, personal information and attention, the extraction architecture reaching further and deeper into 'new territories of human experience'⁹⁹⁰. This conquest relies on the asymmetrical bargaining power of digital platforms, on which an increasingly important part of the population depends in its day-to-day life for work and entertainment, the take it or leave it strategies they adopt, the manipulation of the choice architecture in order to further their capacity to extract behavioural surplus. The 'prediction imperative' pushes also the boundaries of what can be considered as a voluntary exchange to the extent that the digital platforms devise 'means of behavioural modification'⁹⁹¹ through nudging, herding and other forms of influence, a new 'execution architecture' with the aim to generate surveillance revenues by challenging the individuals' 'elemental right to the future tense'⁹⁹². Zuboff argues that 'we now face the moment in history when the elemental right to the future tense is endangered by an pervasive digital architecture of behaviour modification owned and operated by surveillance capital, necessitated by its economic imperatives, and driven by its laws of motion, all of the sake of its guaranteed outcomes'⁹⁹³. As all behaviour becomes predictable, the surveillance capitalists may trade this newly acquired capacity of certainty for profit⁹⁹⁴. Individual autonomy, and the potential of unpredictable behaviour, becomes a 'friction' and a threat to surveillance revenues⁹⁹⁵.

Much of the data collected relates to the digital identity of the consumer and enables companies to draw a pretty accurate individual preferences map and personality traits for each of their clients from even small samples of data and meta-data.

In the era of "machine learning" and Artificial intelligence-assisted pricing the risks of "digital" consumer manipulation may admittedly increase at an industrial scale.⁹⁹⁶ Digital markets exacerbate the above risks, in view of the possibilities they offer of "a vast psychological audit, discovering and representing the desires of society"⁹⁹⁷ and of each individual separately, offering sophisticated evaluation methods that are closely linked to the direct observation of consumer preferences, but also more broadly of a whole range of preferences expressed in social, and private life, through the means of socio-

metric analysis⁹⁹⁸. As mentioned before, Big data enable us to observe, allegedly more accurately, the inner mental states of people and potentially influence the way these form their core preferences. Indeed, “personality correlates” can now be identified that predict the precise ways in which each customer will react to marketing efforts⁹⁹⁹. Emotion detection becomes possible through the emergence of ‘affective computing’, ‘computing that relates to, arises from, or influences emotions’, any conscious, or even unconscious emotion becoming observable behaviour for coding¹⁰⁰⁰. ‘Emotion scanning’ will become the new form of tracking to which are subject users¹⁰⁰¹. ‘Instrumentarianism’, ‘the instrumentation and instrumentalization of behaviour for the purposes of modification, prediction, monetization and control’¹⁰⁰².

Such manipulative potential and of course the possibility that this may occur at a larger scale, in view of the possibilities offered by algorithms, data analysis and artificial intelligence, is clearly motivating digital platforms’ commercial strategies to accumulate behavioural surplus and extract value from it.

These various possibilities of manipulation in digital capitalism call for collective action even if the preferences ‘revealed’ by consumer choice do not indicate the existence of a competition law problem. Competition authorities should be aware of the possibilities of manipulation and should not take for granted that the analysis of the revealed preferences of consumers in defining relevant markets, for instance examining the substitutability of a product vis-à-vis another, will reveal the real boundaries of actual competition. They should envisage that these preferences as revealed or inferred by actual consumer choice may not be the ones consumers really have. This may require a more holistic perspective in competition law taking into account stated preferences as well as evidence of the hypothetical extended preferences of consumers/citizens, as these are revealed in their behaviour in other spheres of their life. This may be easier in the future with the development of sociometrics technologies on the basis of Big Data.

4.5. Moving beyond traditional definitions of market power

The complexity of competition in the digital economy and the different fields on which it takes place raise important challenges as to the prevailing conception of market power used in competition law and economic analysis, which may appear as myopic and not taking into consideration the various dimensions of the competitive game (financialisation, the importance of technological assets and resources, strategies of differentiation and single-homing, exploitation of consumer behavioural biases). In view of the fact that in the economic approach currently followed the existence of some form of market failure is required in most cases in order to trigger enforcement activity by the State, it is

crucial to develop a concept of economic power that takes into account these various dimensions of the competitive game and enables competition law, or other instruments, to achieve the goals set by the policy makers.

Box 4.6. Assessing market power in digital markets: Does access to personal data constitute an important source of market power?

BR CADE usually employs its traditional toolkit to assess market power in the digital economy. When it comes to multi-sided markets, although there is no explicit guide or legislation, there are some particularities that should be taken into consideration, as pointed out by the academic literature and past cases analysed by CADE. For example, interdependent groups of customers that a platform serves and how the uneven effects to these groups deriving from anticompetitive behaviour.

Further, the Brazilian NCA has been paying special attention at the use of data in a way that might unduly restrict competition by companies of the digital economy. In the case *Google vs. Buscapé/Bondfaro*, CADE discussed how big data has become a relevant competitive factor, enabling companies to leverage assets and to extract value from the data to which they have access, by selling information about consumers' patterns and behavior to advertisement companies. In 2016, CADE analyzed a case in which Brazil's leading banks formed a joint venture for credit scoring. Credit scoring companies are multi-sided markets with strong network effects. Financial institutions are the main suppliers of inputs (information about users' financial transactions) to credit bureaux, while they are also the main consumers of the bureaux's products (credit scores). Thus, CADE was concerned the operation would lead to vertical integration. In this case, CADE analyzed whether data (information about consumers) might act as an entry barrier. When data is also a source of market power, a dominant platform can leverage its userbase in order to prevent potential competitors to enter the market, which might lead to market foreclosure. CADE highlighted the risks of foreclosure in both the markets of positive and negative credit scoring, due to the great number of consumers' data held by the proposing banks. Accordingly, one of the remedies agreed by the parties was the commitment that the banks would continue providing data to all credit bureaux, with no discrimination or provision of favorable treatment to their own bureau.

Personal data about user's preferences and characteristics are crucial to inform the creation of content that is better tailored to people's interests and for the development of more efficient products and services. Information harvested by internet companies, thus, can contribute to the reduction of production costs and to quality improvement in such markets. In contrast, precisely because collection and processing of data are determinants of which companies can compete and thrive in digital markets, restrictions in access to data can often lead to a decrease in competition. Lack of data can prevent companies from building a critical database, or from offering goods and services at competitive levels, which makes them less likely to survive in data-driven markets, leading to a decrease in competition.

RU The FAS Russia was dealing with the concept of market power when considering the Bayer/Monsanto merger. Remedies for Bayer/Monsanto merger were drafted taking into account the big data (including the historical data) on climatic, soil and other conditions around the globe. The FAS Russia assumed that having the mentioned data is crucial for business successful development.

That is why the FAS Russia ruled to provide non-discriminatory access to data for the Russian players of agro technological market. Also, the FAS Russia considered cases in relation to big corporations which has access to big amounts of personal data (Google, Apple, Microsoft). At the same time, up to the moment the access to personal data has never been an argument in the antitrust cases considered by the FAS Russia.

CN There are no cases so far concerning operators in the digital platform who enjoy “market power”. According to Article 11 of the Interim Provisions on Prohibiting Abuse of Dominant Market Positions, which will be implemented on September 1, 2019, when determining whether the entity has a dominant position in digital economy, regards can be made to the competitive characteristics of relevant industry, business models, and number of users, network effects, lock-in effects, technical characteristics, market innovation, ability to master and process relevant data, and market power of entities in related markets.

4.5.1. Conceptualizing power in the digital economy: a theoretical perspective

Sociologists and economists have developed different approaches to the concept of power. If for economists, markets are primarily processes for price formation, the price helping to allocate scarce resources in an efficient manner, (market) power being the ability to increase prices and consequently to allocate scarce resources in an inefficient manner, sociologists focus on social relations and institutions in markets, analysing the way market actors interact with each other when producing or exchanging products.¹⁰⁰³ The potential for each of these approaches to deal with vertical, as opposed to horizontal power varies.

From a sociological perspective, in Max Weber’s classic definition, power denotes a situation in which there is “probability that one actor within a social relationship will be in a position to carry out his own will despite resistance, regardless of the basis on which this probability rests”.¹⁰⁰⁴ This definition may present various problems in view of the focus on the volitional element, the “will” of a specific actor, as opposed to the “resistance” of another, thus indicating that some form of coercion is exercised on one actor by another. The concept of coercion is notoriously complex and ambiguous. Most theoretical accounts of coercion appear to be either over- or under-inclusive.

The absence of alternative “reasonable choices” can easily entail a conception of coercion that is too narrow, particularly as applied to exercises of market power. Such a narrow understanding of coercion is advanced by Friedrich A. Hayek. Hayek takes the difference between a free man and a slave as his heuristic starting point in order to argue that “[c]oercion occurs when one man’s actions are made to serve another man’s will, not for his own but for the other’s purpose [...] Coercion implies, however, that I still

1003 For a discussion, see M. Grannoveter, *Society and Economy: Framework and Principles* (Harvard University Press, 2017), 91; R. Swedberg, *An Introduction and Agenda*, in V. Nee & R. Swedberg (eds.), *The Economic Sociology of Capitalism* (Princeton University Press, 2005), 4, 11.

1004 M. Weber, *The Theory of Economic and Social Organization* (1947, Free Press, first published 1922), 152.

choose but that my mind is made someone else's tool, because the alternatives before me have been so manipulated that the conduct that the coercer wants me to choose becomes for me the least painful one."¹⁰⁰⁵ Consequently, Hayek argues that substantial market power or monopoly could rarely result in true coercion. A monopolist could only exercise true coercion if he where, for example, the owner of the only spring in an oasis, leaving other settlers no choice but to do whatever the spring owner required of them if they want to survive.¹⁰⁰⁶ Hayek's conception of coercion is thus clearly unhelpful, as it would only cover threats to deny goods that are crucial to one's existence.¹⁰⁰⁷

By contrast, a broader understanding of the absence of reasonable choices would entail that an extremely tempting offer, such as sharing the profits of a long-term joint venture, may be considered as exercising a pressure similar to a conditional threat by a monopolist of a scarce resource to deny access to this facility at a reasonable rate, to the extent that in both cases the presumed "coercer" is manipulating the incentives (or opportunity costs) that the presumed "coercee" associates with various courses of action, but one may not want that to be considered as a form of economic coercion, as this would eventually lead to a quite broad interpretation of the term, eventually including also situations of mutually beneficial cooperation.

To the extent that the voluntary, or not, character of an exchange may not constitute an adequate criterion to define (economic) power, it may be more relevant to focus on indirect methods of observing power, such as the *process* through which economic power is manifested as well as its various *sources* or various *manifestations* of power deemed relevant for the specific circumstances.

Process-based definitions of power focus on the bargaining process and aim to identify situations in which there is some form of asymmetry or inequality on the ability of the actors to influence each other's course of conduct. In economics, the analysis of bargaining power is intrinsically related to the issue of how actors may divide the joint gains resulting from their cooperation, the so called bargaining problem. Bargaining power will conventionally refer to the relative share of the total surplus gained by an actor in the bargaining problem. What matters is not the distributive outcome as such, for instance that each participant enjoys an equal share of the joint profit, but the fact that each participant has been able to get a payoff equivalent to their next best alternative. Absent this rent from the joint surplus collected by the participants, these will have no incentive to enter into the joint activity at the first place.

Dominant conceptions of economic power also link power to dependence, as 'someone who controls resources that you value has power over you – can cause you to modify your behavior in an attempt to obtain more of those resources than otherwise'¹⁰⁰⁸. Hence, power in the economy may derive from 'dependency arising from some par-

ticular distribution of resources¹⁰⁰⁹. The situation of resource-dependence between two firms may precede their business relationship, coincide with their relation and the contract that incepts such relationship, or arise in the implementation of the relation. We may have a situation of unbalance in the business relationship between two firms, which makes impossible or excessively difficult for one to continue with the business without the other, because of a high degree of interdependence between them, this being seen as equivalent to some form of intra-organizational relation between them. The conceptualization of such relations as forming part of a value chain contributes to this "intra-organizational" understanding of their interdependence. We may have, on the other hand, a resource-dependence created by market conditions precedent to the stipulation of the relation, which forced one of the parties to accept the terms imposed by the dominant firm(s) and undertake specific investments or actions.

Power differentials between the parties to an exchange may not only be assessed on the basis of the individual characteristics of the actors in a dyadic relation, such as the control of a superior technology or that of an indispensable input for the production process, but may also relate to the broader social structure of the exchange, such as the position of the specific entity in the social network to which it is embedded (positional power). As Willer explains, 'power as potential is located in structures', '(s)ubsequently, actors in structures produce power as activity'¹⁰¹⁰. Cook et al., in particular, has focused on the network position of the economic actors in order to determine the power-dependence not in the context of a dyadic relation, but in the context of a network¹⁰¹¹. The topography of networks is particularly important in view of 'the tendency of complex systems to create asymmetric network structures, in which some nodes are 'hubs,' and are far more connected than others'¹⁰¹². Centralised networks provide actors with the necessary levers to extend their influence and thus reach sooner the tipping point towards sustainable dominance, eventually using the networks for their own purposes rather than those that led to the formation of the network at the first place.

Taking a sociological perspective, Cook et al. focus on social structure as a possible source of power, social structure being a configuration of social relations and positions among actors, 'where the relations involve the exchange of valued items (which can be material, informational, symbolic, etc.)'¹⁰¹³. These relations are not only linking actors directly, but also indirectly¹⁰¹⁴. An exchange relation may not thus not only occur

directly between two actors, but relate to more complex exchange networks, viewed as ‘connected sets of exchange relations’¹⁰¹⁵. This calls for an analysis of resource dependence in the context of a network, with the assistance of social network analysis that focuses on the patterns of interaction between actors. Networks analysis forms part of structural analysis, to the extent that it aims to explain phenomena primarily, if not completely, by social structure, however, it cannot only be subsumed to structuralism, to the extent that it also explores the creation and/or maintenance of networks, as well as also emphasizes the role of the individual actors and their strategies, thus bringing to the picture exchange theory¹⁰¹⁶.

In the complex, digital economy, power may take various dimensions than the simple reduction of output (and increase of prices) on which focuses the concept of market power traditionally used by competition law. Hence, there is need to enrich the dimensions of economic power considered in competition law. The next Section will examine whether the traditional concept of horizontal market power may be appropriate for the digital economy, or if it has to be supplemented by other concepts of economic power that take better account of vertical competition.

4.5.2. Is the traditional concept of horizontal market power fit for purpose in the digital economy?

The emphasis put over control over access to data in the digital economy has led a number of competition authorities to re-conceptualise their traditional conception of market power by integrating this data access dimension. For instance, a recent study commissioned by the German Ministry of Economics and Energy¹⁰¹⁷ observes that control over data can be analysed either as superior (comparatively to other horizontal competitors) market power (‘relative’ market power targeted by 20 (3) GWB), or as a source of relational market power in the context of vertical relations, for instance in IoT and after-markets contexts (which can be targeted by 20 (1) GWB). The study even notes that the control over access to data constitutes a more important criterion for the finding of a dominant market position than the financial capabilities of the undertaking (which is criterion relevant for the finding of a dominant position pursuant to § 18 Abs. 3 Nr. 2 GWB) since the financial resources are already subject to competing alternative use through functioning capital markets, while liquid markets for data are still absent and that, in so far as personal data is concerned, the GDPR may prevent the emergence of such liquid data markets from the outset.

1015 Cook et al. 1993, 113 referring to the work of R.M. Emerson, Exchange theory, part II: exchange rules and networks, in J. Berger, P. Zelditch & B. Anderson (eds.), *Sociological Theories in Progress* (Vol. 2, Houghton Mifflin, 1972), 58.

1016 Cook et al. 1993, 114.

1017 Bundesministerium für Wirtschaft und Energie, *Modernisierung der Missbrauchsaufsicht für marktmächtige Unternehmen* (September 4th, 2018), available at <https://www.bmwi.de/Redaktion/DE/Publikationen/Wirtschaft/modernisierung-der-missbrauchsaufsicht-fuer-marktmaechtige-unternehmen.html> (hereinafter *Modernisierung Study*).

This quest for flexibility in conceptualising power conducive to competition law enforcement leads competition authorities to go beyond the traditional perspectives of selling or buying power, first in order to integrate the futurity dimension of the digital economy (the emphasis on innovation), but also in order to be able to bring within the remit of the enforcement activity competition authorities market failures resulting from information asymmetries or more generally bargaining power that are not usually considered as normally falling within the scope of competition law.

4.5.2.1. Selling power

Neoclassical economics is based on resource scarcity. Scarcity entails that any choice as to how resources get allocated – as a result of decisions made by individuals, firms and/or the state – must reckon with the idea that there are alternative uses that would yield valuable outcomes. In economic jargon, the best alternative use corresponds to an ‘opportunity cost’, which the decision maker would want to factor in when choosing how best to allocate what he is endowed with. Ultimately, society would want to adopt an allocation mechanism that is capable of maximising the benefits from consumption of scarce resources over the long term.

Markets, though, are not faultless. As competition authorities have recently converged towards a ‘consumer welfare’ paradigm, however fuzzy its definition is, the focus has been on market power at the selling side (selling power), whereby competitive rivalry is lessened so that consumers are left with little choice than to buy on the conditions (price or non-price) imposed by the firm(s) holding market power. Hence, the idea is the important thing is that market power may impact on consumers (intermediary or final). Under these circumstances, consumer detriment might arise due to higher prices (leading to lower quantity sold), lower quality and variety on offer. Competition law, with its various provisions, is meant to address such market failures in order to preserve well-functioning markets by either protecting (through ex-ante intervention and indirect deterrence), or reinstituting (through ex-post intervention and direct deterrence) competitive rivalry.

The inherent ambiguity in what underpins a position of substantial market power means that intervention under competition law is triggered primarily where market power is likely to be significantly increased through external growth, such as via mergers, joint ventures or other forms of coordination among firms. Moreover, enforcement can also be triggered where an alleged conduct undertaken by an already dominant firm is likely to entrench its position of substantial market power by cutting out rivals from a large chunk of the addressable market. The idea is that, absent the alleged conduct, the large portion of demand served by the dominant firm would have been more ‘contestable’; that is, the alleged conduct has made it more difficult for customers to be able to switch to a rival’s product if they so preferred.

4.5.2.2. Buyer power and monopsony

A typical definition of buyer power is the following one provided by Roger Noll:

“[B]uyer power” refers to the circumstances in which the demand side of a market is sufficiently concentrated that buyers can exercise market power over sellers. A buyer has market power if the buyer can force sellers to reduce price below the level that would emerge in a competitive market. Thus buyer power arises from monopsony (one buyer) or oligopsony (a few buyers), and is the mirror image of monopoly or oligopoly¹⁰¹⁸.

In the standard model of monopsony, the supply side of a market is perfectly competitive and is represented by an upward-sloping supply curve. As a mirror image of a monopolist’s behaviour, a monopsonist can take advantage of his market power by reducing his demand. The lower price obtained by the buyer reflects the lower marginal cost of supply.

What are the competitive effects of buyer power and monopsony power¹⁰¹⁹? With regard to the upstream side, as the monopsonist restricts its input purchases to reduce prices below competitive levels, there might be allocative inefficiency and the buyer may extract supplier surplus. With regard to the downstream side, there is no allocative inefficiency if the monopsonist discriminates perfectly. Consumers do not benefit though from reduced input prices as these do not lead to reduced output prices that are passed to output buyers, to the extent that “the monopsonist may control the *price* it pays for an input but cannot control the *quantity* of the input offered for sale at that price”¹⁰²⁰. Buyer power may also result in “waterbed effects” or “spiraling effects”. The “*waterbed effects*” may result, for instance, from the fact that buyer power could lead to a reduction of marginal costs and lower input prices for the entity with buyer power, which sees its output rising, while at the same time buyer power raises the input prices of the competitors of the entity which do not dispose of buyer power, as the reduction of prices has to be passed on to someone else, which may lead them to increase their prices, thus affecting the final consumers.¹⁰²¹

Although monopsony is considered as the mirror image of monopoly, buyer-side conduct is regularly treated more leniently than equivalent conduct on the selling side. This relies on the idea that serving large buyers may involve lower distribution costs and lower production costs, leading to important discounts, as the larger the buyer the more

1021 On the “waterbed effects,” see, R Inderst & T Valletti, ‘Buyer Power and the “Waterbed Effect” (2011) 59(1) Journal of Industrial Economics, 1-20; P Dobson & R Inderst, ‘Differential Buyer Power and the Waterbed Effect: Do Strong Buyers Benefit or Harm Consumers?’ (2007) 28(7) ECLR, 393-400; A. Majumdar, Waterbed Effects and Buying Mergers, CCP Working Paper 05-7 (2007).

credible would be its threat to integrate backwards and produce the good itself¹⁰²².

One may also distinguish between buyer power, which denotes the ability of buyers to obtain advantageous terms of trade from their suppliers and countervailing power, which characterizes the presence of strong buyers mitigating or even fully averting adverse consequences for consumer surplus or total welfare that would otherwise arise from the exercise of market power at the supply side. Countervailing power on the buyer side may be an important force offsetting suppliers' increased market power¹⁰²³. The economic analysis of bilateral monopoly or oligopoly, the situation where a lawful monopolist confronts a lawful monopsony, does not offer clear directions. While some authors argue that bilateral monopoly produces welfare effects that are superior to those of monopoly or monopsony and that it does not raise any competition concerns¹⁰²⁴, others doubt on the possibility of bilateral bargaining to reliably reach an efficient outcome, because of the pervasive presence of private information and incomplete contracts¹⁰²⁵.

This debate on buyer power or monopsony is particularly important in the context of the emergence of large and powerful digital platforms that benefit from a bottleneck position at the middle of the digital value chain and may be seen as exploiting their power in order to extract unfair terms from their suppliers, or more generally the members of their ecosystem, including dependent self-employed labour force, and capture most of the surplus value generated by the value chain, thus leading to a fall in the labour share of capital¹⁰²⁶. Through the exercise of monopsony or buyer power, these digital platforms develop also their ability to impose a lower level of privacy protection to their users, in the sense that the activity of harvesting data of digital platforms may be conceptualised as a form of purchasing of personal (or non-personal data), the users benefiting from 'free' services in return. The role of competition law in taming the buying power or monopsony of digital platforms in these various markets, and in particular labour markets¹⁰²⁷, sometimes assisted by digital platforms' exclusionary strategies, such

as no-poaching or non-compete agreements¹⁰²⁸, or by the expansion of the heteromation process¹⁰²⁹, is a hotly debated issue in competition law and economics scholarship.

4.5.2.3. Can existing market power concepts take into account innovation effects?

Competition in the digital era is marked by the idea of futurity, one dimension of which is the emphasis put on the impact on innovation. Competition authorities are increasingly geared towards protecting competition in innovation, thus considering that dynamic efficiency constitutes the most important source of welfare. welfare, it is possible to highlight the (arbitrary) categorical thinking implicit in the trade-offs. The interests of future 'consumers' are assumed to coincide with the revealed preferences of the current 'consumers', for instance regarding the direction of innovation that is socially valuable, notwithstanding any evolution of the values presently prevailing in society, the technologies available, or of what are the requirements of the rules of the prevailing social contract. This monocentric focus on the preferences of actual consumers for innovation, broadly defined, may explain why competition authorities have developed concepts that implement the 'relevant market' tool, when assessing the future effects of mergers or other anti-competitive practices on consumers, by developing concepts such as 'innovation markets'.¹⁰³⁰

The concept has nevertheless been subject to a number of criticisms: first, R&D is only an input to the production of goods and services and competition law analysis should focus on outputs, the actual supply of future goods and services; second, economic

Mergers in Labor Markets (April 2019). Indiana Law Journal, Vol. 94, 2019 ; U of Penn, Inst for Law & Econ Research Paper No. 18-8. Available at SSRN: <https://ssrn.com/abstract=3124483> ; E. A. Posner, G. Weyl & S. Naidu, Antitrust Remedies for Labor Market Power, (2019) 132 Harvard Law Review 537

1028 In 2010, the US DOJ entered a settlement with major digital platforms, such as Apple, Google, and Adobe, concerning their no-poaching or non-competition agreements in which they agreed not to hire each other's employees: See Press Release, Office of Pub. Affairs, U.S. Dep't of Justice, Justice Department Requires Six High Tech Companies to Stop Entering into Anticompetitive Employee Solicitation Agreements (Sept. 24, 2010), available at <https://www.justice.gov/opa/pr/justice-department-requires-six-high-tech-companies-stop-entering-anticompetitive-employee> . The US DOJ and the FTC also published specific guidance on this issue: US DOJ & FTC, Antitrust Guidance for Human Resource Professionals (October 2016), available at <https://www.justice.gov/atr/file/903511/download> . A number of recent antitrust cases made similar findings: see, Garrison v. Oracle Corp., 159 F. Supp. 3d 1044, 1053–55 (N.D. Cal. 2016); United States v. eBay, Inc., 968 F. Supp. 2d 1030, 1033 (N.D. Cal. 2013); In re High-Tech Emp. Antitrust Litig., 985 F. Supp. 2d 1167, 1172–73 (N.D. Cal. 2013); see also In re Animation Workers Antitrust Litig., 123 F. Supp. 3d 1175, 1181–84 (N.D. Cal. 2015).

1029 The process of heteromation was coined by Hamid Ekbai and Bonnie Nardi as referring to a process in which activities that were previously taking place within the firm are outsourced to the firms' users/customers who enter into activities that contribute to the value with little or no compensation. Users are seduced into (gaming, social media...) or forced to (self-service, gatekeeper apps like Academia.edu...) participation in heteromated labour that provides surplus value without adequate compensation: H.B. Ekbai & B.A. Nardi, Heteromation (MIT press, 2017). Some authors hinted to the idea that the process of personal data harvesting may be considered as involving a form of labour from the part of the users of the platforms: I. Arietta Ibarra, L. Goff, D.H. Hernández, J. Lanier, E.G. Weyl, Should We Treat Data as Labor?, (May 2018) Papers and Proceedings of the American Economic Association 1, available at https://papers.ssrn.com/sol3/papers.cfm?abstract_id=3093683 .

1030 See RJ Gilbert and SC Sunshine, 'Incorporating Dynamic Efficiency Concerns in Merger Analysis: The Use of Innovation Markets' (1995) 63 Antitrust Law Journal 569.

theory does not provide a solid empirical basis on the assumption that the decrease in the number of firms engaged in R&D will affect negatively innovation (the link between market structure and innovation), as the elimination of redundant expenditure, the reduction of costs and the possibility for the firm to fully capture the results of the R&D programme might accelerate the process of innovation; third, the sources of R&D may be difficult to identify as discoveries may come from unexpected places. An “innovation market” approach may not provide an appropriate framework to the extent that it does not take into account the possibility of drastic innovation and the possible entry of undertakings that are not presently active in the specific industry or market, but may have some technological capabilities that could enable it to constitute a possible competitive constraint in innovation competition¹⁰³¹.

In some recent merger cases concerning the seed/agrochem sector, the European Commission took a broader perspective and employed the concept of “innovation space” and “industry” when assessing the possible effect of the merger transaction on innovation¹⁰³². According to the Commission, when analysing the effects on innovation it becomes important to assess the impact of the transaction “at the level of innovation efforts by the Parties and its competitors”¹⁰³³. The assessment of innovation competition follows three steps:

“(349) First, the assessment of innovation competition requires the identification of those companies which, at an industry level, do have the assets and capabilities to discover and develop new products which, as a result of the R&D effort, can be brought to the market.

(350) Secondly, it is also relevant to identify and analyse those spaces in which innovation competition occurs in the crop protection industry. The R&D players do not innovate for all the product markets composing the entire crop protection industry at the same time. They also do not innovate randomly without targeting specific spaces within that industry. When setting up their innovation capabilities and conducting their research R&D players have specific discovery targets ([...]).

(351) A given discovery target is based on lead crops and lead pests and may thus comprise AIs that can be used in several downstream formulated product markets (for example chewing Lepidopteran insecticides, broadleaf herbicides). The spaces where innovation competition takes place are thus broader than an individual downstream crop protection market, but are nonetheless small. In fact, in light of increasing regulatory hurdles, which require crop protection products to be ever more selective, the innovation spaces in the crop protection industry are getting ever smaller: the innovation output tends to be confined to ever narrower spaces from which it is more difficult to adapt the innovation to other purposes.

1031 R. J Gilbert, ‘Competition and Innovation’ in Wayne D Collins (ed) 1 ABA Section of Antitrust Law, Issues in Competition Law and Policy 577, 583 (American Bar Association 2008) Ch 26.

1032 EU Commission Decision, CASE M.7932 Dow/Dupont (2017), paras 348-352.

1033 Ibid., para. 348.

(352) In conclusion, in order to assess innovation competition, the Commission will both consider metrics of innovation taking place at industry level, as well as innovation taking place in spaces consisting of groupings of crop/pest combinations [...] [areas where the parties' activities overlapped]¹⁰³⁴.

In its assessment of the *Dow/Dupont* merger the Commission focused both on innovation competition "at the level of innovation spaces within the crop protection industry and on innovation competition at the industry level"¹⁰³⁵. More specifically, the Commission focused on the line of research the merging companies were active, the latter concept comprising "the set of scientists, patents, assets, equipment and chemical class(es) which are dedicated to a given discovery target whose final output are successive pipeline [products] targeting a given innovation space"¹⁰³⁶.

A closely related debate is that on the way to integrate potential competition in the rapidly evolving digital industry. The debate was generated by the allegations that many established companies proceed to 'killer acquisitions' buying out smaller start-ups or small and medium undertakings with the aim to discontinue the development of the targets' innovation projects that may challenge their dominant position, thus pre-empting future competition¹⁰³⁷. Indeed, if an additional investment in R&D by a potential entrant reduces the expected profits of a rival (and vice versa), because of its business stealing effect, then a merger between these two firms may internalise this negative externality, and reduce innovation.

Actual competitors are considered in the operation of the definition of a relevant market that may be affected by the specific anticompetitive conduct under examination. For instance, a merger where the target firm is not competing in the same relevant market of the acquiring firm can still give rise to a significant impediment of effective competition (SIEC), whether non-coordinated or coordinated, if there is a realistic prospect that the former could decide to enter the market in the near future but for the merger in question. The threat of entry is stronger where the target company already has, or is very likely to acquire, assets that could facilitate entry. Evidence of actual plans to enter at an advanced stage would point towards that conclusion. However, the likelihood of a SIEC is reduced if there are a sufficient number of potential competitors left able to discipline actual competitors. Usually competition authorities have taken a relatively narrow time scale for considering potential competition. For instance, under the EU Merger Guidelines, to be an effective threat, potential competitors should be able to enter within two years and on a sufficient scale. This can lead to ignore the possibility of potential entry into a market if the time scale of this entry may be longer than two years. The difficulty resides in finding evidence that the potential competitors may have such plans and that these are credible enough to influence the competitive strategies of the merging firms.

1034 Ibid., paras 349-352.

1035 Ibid., para. 1956.

1036 Ibid., para. 1958.

1037 Some analysis in the pharmaceutical sector argues that more than 6% of acquisitions every year are 'killer acquisitions': see C. Cunningham, F. Ederer, and S. Ma, *Killer Acquisitions* (2018), available at: http://faculty.som.yale.edu/songma/files/cem_killeracquisitions.pdf.

It is thought that extending the time scale to a longer period than two years may lead to a high degree of uncertainty and increase the risk of arbitrary decision-making.

However, there can be circumstances where the threat of potential competition is less palpable but where a merger may be thought to give rise to a SIEC. It is often argued that the valuation of internet start-ups is very subjective due to the elusive nature of the key intangible asset underpinning their business model, that is, the acquisition of a large customer base. To this end, firms typically attract users by offering their services for free, thus incurring material operational losses for a number of years before the prospect of turning the venture into a profitable business. Furthermore, it is argued that once the customer base is in place, it is easier to launch new services thanks to the availability of a critical mass. Similar conclusions may be reached with regard to the possibility of a market becoming contestable in a medium term (e.g. five years), this assessment being based on the “idiosyncratic rent-earning resources” and capabilities, such as specific innovation and technological capabilities, that few other undertakings may have, that could provide them an advantage in entering a specific market, in particular if the structure of the industry is that of a global oligopoly. In this case, it is possible to argue that such resources and capabilities should be taken into account, even if there are no established plans or plans in the making to enter the specific market. But of course, such an approach will be subject to the criticism of considerably expanding the discretion of competition authorities to intervene, or not.

In this context, some competition regulators, in particular the European Commission, have looked beyond the R&D pipeline to explore the dynamic resources and capabilities of the specific firms to innovate and the development of specific “lines of research.”¹⁰³⁸ The Commission has looked, for instance, to investment in basic R&D that may with some degree of probability become eventually profitable, even if this probability remains limited, for instance 10%. This approach seems to expand both the locus and the time period that is usually considered in assessing actual or potential competition, as the Commission has examined the overlaps between the parties, not only at the level of innovation spaces, by looking to “early pipeline projects” and “lines of research,” but also at the level of the industry. The Commission has indeed taken into account the global characteristics of R&D organisations, that is, the resources, personnel, facilities, and other tangible and intangible assets dedicated to research and development.¹⁰³⁹ If such a broader analysis may be perfectly justifiable in order to assess the innovation effects of the merger transaction and reduce the likelihood of “killer acquisitions,” it would also make sense to adopt a similarly flexible perspective when assessing potential entry when this could constrain the pricing strategies of the merged entity. Unless one is to consider that price effects would merit a different approach than innovation effects. This could make a difference in some cases, in particular if it is reasonable to expect that the future competitor may have the incentives and ability to enter the market in the medium term, on the basis of its tangible and intangible assets, idiosyncratic resources and

1038 A theory that has, for instance, influenced the approach of the European Commission in Dow/DuPont: European Commission, Case M.7932 Dow/DuPont (2017).

1039 Ibid., para. 1957.

capabilities, possibly in view of some history of previous expansion in other geographic markets.

4.5.3. Vertical non-structural power: variations on a theme

The theory of non-structural market power has been criticized by some authors as not being sufficiently substantial to constitute market power under competition law, and that it should therefore be excluded from competition law assessment¹⁰⁴⁰. Two reasons are advanced for this criticism: (i) enforcement agency budgets and judicial resources are scarce and thus, it does not make sense to squander them in attacks on market power over low sales volumes, as it is the case for relational power and (ii) there are no procedures or specific methodologies/metrics for measuring the extent of market imperfections, thus permitting the intervention of the competition authority in situations of intermediation or significant architectural or positional power. These issues notwithstanding vertical power becomes particularly important in the rapidly evolving environment of the digital economy, in which futurity and the potential for disruption plays a considerable role in driving the market valuation of the various players and therefore potential competition takes centre-stage, sometimes being more important than actual competition. This is particularly the case if the focus shifts from efficiency to the capture of surplus value in digital value chains, which brings in a fairness perspective. It becomes therefore essential to explore in more detail the different forms of non-structural power that have been put forward in the various competition authorities' reports and the literature.

4.5.3.1. Bottleneck or chokepoints power

Traditional conceptions define monopoly power by reference to the capacity it confers to exclude rivals: US economist Edward Mason explained the different conceptions of monopoly power in law and in economics, by opposing the neoclassical price theory view of market power as the ability to raise prices profitably and reduce output, to the legal conception of monopoly power as the ability to exclude competitors and to affect the competitive process¹⁰⁴¹.

New industrial economics have focused on the possibility of incumbents to employ strategic barriers to entry in order to exclude or marginalise rivals and thus be able to raise prices and harm consumers.¹⁰⁴² Professors Krattenmaker, Lande and Salop have argued that there are two methods of exercising market power corresponding, respectively, to the 'power to control price' and 'power to exclude competitors' distinction¹⁰⁴³:

1040 B Klein, 'Market Power in Antitrust: Economic Analysis After Kodak' (1994) 3 Supreme Court Economic Review 43.

1041 See, Monopoly in Law and Economics' [1937] 47 Yale Law Journal 34

1042 See, A Jacquemin, *Sélection et Pouvoir dans la nouvelle économie industrielle* (Economica, 1985), 118.

1043 TG Krattenmaker, RH Lande and SC Salop, 'Monopoly Power and Market Power in Antitrust Law' (1987) 76 Geo L J 241, 248.

“First, the firm or group of firms may raise or maintain price above the competitive level directly by restraining its own output (‘control price’). The power to control price by restraining one’s own output is the usual focus of Chicago School antitrust analysts. For this reason, we denote the power to control price profitably, directly by restraining one’s own output, as classical [...] market power.

Second, the firm or group of firms may raise price above the competitive level or prevent it from falling to a lower competitive level by raising its rivals’ costs and thereby causing them to restrain their output (‘exclude competition’). Such allegations are at the bottom of most antitrust cases in which one firm or group of firms is claimed to have harmed competition by foreclosing or excluding its competitors. We denote this power as exclusionary [...] market power. Consumer welfare is reduced by the exercise of either [classical] or [exclusionary] market power. [...]

Exercising either type of power reduces allocative efficiency and transfers wealth from consumers to the owners of the firms exercising monopoly power. In addition, for [exclusionary] market power, production efficiency also is reduced”.¹⁰⁴⁴

The distinction is important as “anticompetitive, exclusionary, market power occurs when an excluding firm successfully achieves two related goals”: first “by denying inputs to its rivals, the excluding firm materially raises its rivals’ costs”; second, “by thus precluding the competitive check on its price and output decisions that those rivals provide, the excluding firm thereby gains the power to price in its output market above the competitive level. [...]”.¹⁰⁴⁵ Proof of either power should, according to the same authors, lead to the finding of market power or a dominant position.

An important implication of exclusionary market power concept is that it leads to a different approach from neo-classical market power or ‘power over price’ in order to estimate the existence of a dominant position, the competition authority first identifying the allegedly exclusionary conduct, and then analyzing market power.

Controlling a bottleneck or a ‘chokepoint’ in a network, cutting adversaries off from network flows¹⁰⁴⁶ may qualify as a dimension of exclusionary power, which we will call ‘bottleneck power’. Bottleneck power has been a particular concern in view of the ability of platforms to adopt strategies such as exclusive contracts, bundling, or technical incompatibilities in order to restrict entry of competitors, in particular in the digital economy. Bottleneck power does not only result from supply-side conditions, such as the control of an essential facility or input, necessary for competing producers if they are not to be excluded or marginalised from the market. It may also ensue from demand-side conditions, such as the propensity of consumers to single-home, and thus, not to use more than one platform for the specific functionality¹⁰⁴⁷. One may also envisage differ-

ent forms of bottlenecks that may emerge from changes in technology or the creation of new commodities, and scarcities, as bottlenecks in the digital economy may evolve in view of the technological developments.

4.5.3.2. 'Intermediation' power

The pivotal role of digital platforms and information intermediaries in the new economy has attracted the attention of competition authorities and has renewed the discussion over the sources of economic power, beyond the narrow view of market power as the ability to raise prices and reduce output profitably. The German Ministry for the Economy and Energy commissioned to a group of academics a report on the Modernisation of competition law published in September 2018¹⁰⁴⁸. This report followed the 9th amendment of the '*Gesetz gegen Wettbewerbsbeschränkungen*' (GWB, Law against Restraints of Competition) in which the legislator had implemented a more precise definition of the assessment criteria for the finding of a dominant position of platforms and networks. The study's aim was to clarify whether the rules on abuse of dominant positions are sufficiently clear and effective and whether the particular challenges of the new economy could be sufficiently dealt with by §§ 18 and 19 GWB (the German equivalent to 102 TFEU), or should also be met through the use of §20 GWB, a provision prohibiting certain conducts of undertakings with relative or superior (non-structural) market power. Indeed, § 20 GWB is a stricter national provision for the protection against unilateral abuses, as is allowed pursuant to Art 3 (2) Reg. 1/2003. According to § 20 (1) GWB abuses of relational market power (in vertical relations) are prohibited while 20 (3) GWB proscribes exclusionary practices by an undertaking with comparatively more market power than its competitors. The German courts (BGH) have imposed very restrictive requirements on the applicability of § 20 (3) GWB.

The study's starting point was the important role of new 'information intermediaries' (search engines, price comparison platforms, booking portals and trading platforms) which collect, sort and rank (at least parts of) the available online information for consumers and occupy a central position in an increasing number of markets. According to the *Modernisierung* Study, 'information intermediaries' provide the consumers with all kinds of information about the quality and reliability of different offers and transaction partners and create – following the evaluation of user data attractive matching options. Indeed, the efficient 'matching' of information-supply according to respective consumer preferences has become the core of many digital platforms. Moreover, consumers' options to check the quality of the 'intermediation intermediary' itself are limited. Therefore, the Report found that the increasing use of 'information intermediaries'

ture and Antitrust Subcommittee (Report, May 15th, 2019), available at <https://research.chicagobooth.edu/-/media/research/stigler/pdfs/market-structure-report.pdf?la=en&hash=E08C7C9AA7367F2D612DE24F814074BA43CAED8C> as 'a situation where consumers primarily single-home and rely upon a single service provider (a "bottleneck"), which makes obtaining access to those consumers for the relevant activity by other service providers prohibitively costly'.

1048 Bundesministerium für Wirtschaft und Energie, Modernisierung der Missbrauchsaufsicht für marktmächtige Unternehmen (September 4th, 2018), available at <https://www.bmwi.de/Redaktion/DE/Publikationen/Wirtschaft/modernisierung-der-missbrauchsaufsicht-fuer-marktmaechtige-unternehmen.html> (hereinafter Modernisierung Study).

caused sellers of goods and services to become dependent on access and visibility of their offers on these intermediaries, that thus function as gate keepers in a variety of different contexts. The economic power that an intermediary disposes in relation to a seller or service provider depends on the extent of consumers utilizing (solely) that intermediary and on the quality and availability of alternative intermediaries. If a supplier of goods and services is dependant from a digital intermediary, then this intermediary does not face any (significant) competitive constraints. This can be the case even if the intermediary has lower market shares than those traditionally required for the finding of dominance. Even if there are potential substitute platforms that consumers may switch to, information intermediaries may act independently of any competitive constraints, if consumers' reaction (e.g. leaving the platform) to price increases is stronger than decreases in quality (e.g. rankings that are not based on user preferences) and/or if consumers do not systematically multi-home and compare the results. This can lead to market failures that could be conducive to competition law enforcement, in particular as digital platforms and intermediaries may employ a variety of strategies to reduce inter-platform competition and artificially induce the tipping of the market. These can be exclusionary strategies towards horizontal competitors (at various segments of the value chain), for instance, through impeding multi-homing, certain smart pricing structures, conduct increasing the switching costs for consumers, self-preferencing in the context of a vertically integrated platform), or the development of conglomerate strategies that would enable digital platforms to gather a lot of data over consumers, and combine them so as to create very detailed user profiles, thus reducing the contestability of the intermediation power of digital platforms.

It is interesting that the study includes information asymmetries among the market failures that should be taken into account in competition law enforcement in the digital economy. According to the *Modernisierung* Study there are situations, in which an information intermediary may abuse information asymmetries vis-a-vis consumers for its own advantage and thereby exclude competitors with better services from the market, even if the incumbent does not dispose of a market share of at least 30-40%. This type of power can hardly be captured under traditional the assessments of market power (selling or buyer power). According to the Report, the broad definition of a dominant position in EU and German competition law as the 'possibility to act independent of any competitive constraints' may appear in conflict with the structural minimal requirements (minimum market shares) approach and raises the question as to whether a dominant position can be inferred from the ability to exclude competitors through a systematic abuse of information asymmetries.

In order to deal with this gap, the *Modernisierung* Study puts forward the concept of 'intermediation power'. Usually intermediation power can be seen as a special form of seller power, namely intermediation power on the market for the supply of intermediation services to suppliers of goods and services. However, this approach does not integrate the dependency of suppliers of goods and services on the intermediation service. For the authors of the Study, the concept of intermediation power should stand explicitly as

a third form of power, in addition to buyer power and seller power, in § 18 GWB and Art 102 TFEU. It would apply when there is a direct market relation between the intermediation platform and the supplier. Hence, they suggest that the criteria for the assessment of the market position of networks and multi-sided platforms enumerated in § 18 Abs. 3a GWB should be supplemented with a criterion relating to the ‘importance of the platform in the intermediation between suppliers and consumers’. Furthermore, § 20 GWB should be developed in order to encompass (relational) intermediation power.

However, moving beyond its conception as a form of relational power, the Study also argues that ‘intermediation power’ may also exist even if there is no market relation between the intermediation platform and the supplier (for instance in the case of pure information intermediaries, like specialised search engines which just provide users with aggregated publicly available information). The Study notes that ‘a significant ability to steer “information consumers” to certain offers, and thereby to affect – and possibly restrain – competition’ constitutes a possible source of ‘intermediation power’. The Study notes a gap in the enforcement of competition law as 102 TFEU/§§ 18, 19 GWB only encompass the dependency of undertakings on a ‘information intermediary’ indirectly, and only if there is a dominant position in relation to the user side (consumers) that is extended through abusive conduct to neighbouring markets. Thus, if the concept of intermediation power is to encompass also these situations, § 18 Abs. 1 GWB and in § 20 Abs. 1 GWB should clarify that intermediation power does not necessitate a market relation between intermediary and undertakings.

The *Modernisierung* Study also notes that unfair competition laws may constitute a tool for dealing with deceptive practices independent of any finding of market power (under § 3 and 5 UWG in Germany). It is also observed that the EU-Commission made suggestions regarding transparency duties for digital platforms towards commercial users, irrespective of any finding of market power (with the adoption of the Platform to Business Regulation), and they note also proposals for the amendment of the Directive on Consumer Rights to improve transparency duties towards consumers. For instance, online-Marketplaces should be obliged to reveal the essential ranking parameters, the applicability of consumer protection laws and the identity of the contractual partner (whether the consumer concludes a contract with the platform operator or with a third party). The Study noted that information asymmetries should be dealt with the parallel development of unfair competition laws, consumer protection laws and contract laws, but that insofar as digital platforms dispose of significant market power, transparency duties and contractual duties alone will not suffice for the protection of competition. Hence, the Study emphasises the fact that infringements of unfair competition laws, consumer protection laws and contract laws may constitute an infringement of competition law provisions, should the other criteria for these provisions being satisfied (*‘Missbrauch durch Rechtsverstoß’* or alternatively *‘Konditionenmissbrauch’*, when contractual terms imposed fall short of mandatory legal requirements). The Study also noted the utility of the new § 32e Abs. 5 GWB which foresees that the Bundeskartellamt may conduct sector inquiries if there is a reasonable suspicion that significant, long lasting

and repetitive infringements of consumer protection laws has taken place harming the interests of many consumers and the opening of such a sector inquiry on October, 24th 2017 with regard to online price comparison platforms.

4.5.2.3. Superior bargaining power

Concerns over the rising power of digital platforms have led some competition authorities to envisage the adoption of new rules on superior bargaining power, these rules either forming part of competition law statutes or of other functional equivalents.¹⁰⁴⁹ These different rules stay relatively opaque as to the definition of the concept of superior bargaining power. The common characteristic (and presumably) advantage of these provisions being that they may potentially impose competition law related duties to undertakings not disposing of a dominant position or a significant market power, for unilateral conduct, which would have otherwise not been subject to competition law related duties under the traditional rules of abuse of a dominant position¹⁰⁵⁰.

The concept of superior (or unequal) bargaining power is also a well-known concept in the fields of contract law and unfair competition law, where it has given rise to a considerable literature attempting to unveil its theoretical underpinnings.¹⁰⁵¹ Authors usually contrast the use of this concept in these areas of law, where the focus is on the unfairness of the process of exchange, with the efforts to integrate this rule in the field of competition law, where the emphasis is usually put on outcomes, such as efficiency or consumer welfare¹⁰⁵². The underlying objective of contract law or unfair competition statutes consists in regulating the contest between contracting parties and ensuring a relatively equalized landscape of bargaining capacity, bargaining power being interpreted as the interplay of the parties' actual power relationship in an exchange transaction.¹⁰⁵³ On the contrary, competition law defines bargaining power more generally, in terms of the ability of an undertaking to introduce a deviation from the price or quantity obtained from the competitive situation in the market in which the transaction takes place. In this context, buying power denotes the ability of a buyer to achieve more favourable terms than those available to other buyers or what would otherwise be expected under normal competitive conditions. This approach emphasizes the gain

1049 For a comparative analysis of rules on superior bargaining power, see ICN, Report on Abuse of Superior Bargaining Position (2008), available at <http://www.internationalcompetitionnetwork.org/uploads/library/doc386.pdf>. See, the recent letter of the UK CMA chair

1050 See the suggestions in the Furman report

1051 See in particular S. N. Thal, *Inequality of Bargaining Power Doctrine: The Problem of Defining Contractual Unfairness*, (1988) 8 Oxford J. Legal Stud. 17; M. J. Trebilcock, *The Doctrine of Inequality of Bargaining Power: Post-Benthamite Economics in the House of Lords* [1976] University of Toronto L. J. 359; L. A. DiMatteo, *Equity's Modification of Contract: An Analysis of the Twentieth Century's Equitable Reformation of Contract Law* (1998) 33 New Eng. L. Rev. 265; and more recently A. Choi and G. Triantis, *The Effect of Bargaining Power on Contract Design* [2012] Va. L. Rev. 1665.

1052 See, P. Akman, *The Concept of Abuse in EU Competition Law: Law and Economic Approaches* (Hart Pub., 2012), 170-184.

1053 Yet, it is important to note that regulatory interventions in order to rebalance contractual inequality are still designed as exceptions to the principle of the freedom of contract and the certainty of the contract, especially in B2B contracts, where a very limited power to rebalance the contractual arrangement is generally left to the discretion of the judge.

resulting from the presence of bargaining power relative to a situation in which it is absent (not necessarily that of perfect competition),¹⁰⁵⁴ focusing on market structure and concentration.¹⁰⁵⁵

The debate usually takes a more philosophical dimension, the main argument put forward by the opponents to the integration of the concept of ‘superior bargaining power’ in competition law assessment, being that competition law aims exclusively at the maximization of welfare effects, and should not include considerations of fairness, allegedly served by the doctrines of economic duress, unconscionability and undue influence in English contract law.

Box 4.7. South Africa and abuse of buyer power

The Competition authorities in South Africa have not yet developed a policy on the digital economy. Although South Africa’s recent Competition Amendment Act 18 of 2018 has not specifically been designed to address digital markets, some features could have particular relevance for the authorities’ assessment of digital markets. On-line trading platforms have been included in a preliminary list of sectors to which a newly introduced prohibition against abuse of buyer power applies. The Amendment Act also strengthens market inquiry provisions. The South African Government applies a National Integrated ICT Policy. It outlines the overarching policy framework for inclusive digital transformation and includes strategies such as a national broadband policy.

With regard to the definition of the relevant concept of economic power, some scholars have tried to draw a clear boundary between bargaining power, which is considered a contract law issue, and monopoly power, which is viewed as a competition law issue, what we will call the separability thesis. In particular, Trebilcock believes that it is fundamental to differentiate ‘situational monopolies’ from ‘structural monopolies’¹⁰⁵⁶. Situational monopolies are transitory states of imbalance in the bargaining position of the parties to an agreement, which can be subject to exploitation. The ‘situational monopolist’ (in Trebilcock’s terms) may take advantage of the business partner by charging prices that are higher than its ‘reference price’. For instance, Trebilcock imagines a situation where ‘A has violated his own reference price in opportunistically taking advantage of B’s temporary dependency’¹⁰⁵⁷. For Trebilcock, these monopolies should be regulated

by contract law. On the other hand, structural monopolies are those that antitrust law should target, as the dominance of the monopolist is market-wide and non-transitory. Here, the dominant firm enjoys a market power that precedes the negotiation of the specific bargain and that impacts on all the market actors¹⁰⁵⁸. However, it has already been noted that when the relevant market is narrowly defined, as it may happen in EU competition law, the two situations are indistinguishable and therefore the distinction may lose significance¹⁰⁵⁹. Trebilcock maintains that while the problem of competition law is to determine and remedy to market failures, contract deals with contracting failures, which in the particular case of duress, relates to the coercion of voluntariness that may happen in 'situational monopolies'. This is particularly the case for long term contracts where exploitation of a 'bilateral monopoly' is likely to occur¹⁰⁶⁰.

Several competition law regimes may be ambiguous as they may incorporate provisions regarding unilateral conduct involving 'unfair business practices' or 'unfair contract terms'. Inequality of bargaining power has also been used by the European Commission in several cases, especially to deal with situations of economic dependence. According to Akman, '(t)he lack of freedom to choose between different suppliers as a result of the dominant undertaking's conduct' has been a concern in Article 102 TFEU cases in the EU¹⁰⁶¹. Akman identifies two main problems that may arise of the interplay between competition law and the contract law doctrine of economic duress:

1058 Id. 96. "publisher": "Harvard University Press", "number-of-pages": "324", "source": "Google Books", "abstract": "Our Legal System is committed to the idea that private markets and the law of contracts that supports them are the primary institutions for allocating goods and services in a modern economy. Yet the market paradigm, Michael Trebilcock argues, leaves substantial room for challenge. For example, should people be permitted to buy and sell blood, bodily organs, surrogate babies, pornography, or sexual favors? Is it fair to allow people with limited knowledge about a transaction and its consequences to enter into it without guidance from experts? Finally, do people always know their own preferences, many of which may be socially conditioned? These are only a few of the issues Trebilcock explores in this sweeping analysis of the private ordering model of contract law and the major theoretical camps critiquing it, including the communication and the feminist. He examines the implication that the private ordering paradigm simultaneously promotes autonomy and welfare values, and argues that in many contexts the convergence of these values is much more contestable than its proponents claim. The book treats all the conflicting perspectives with care, acknowledging both their strengths and their weaknesses, and using them to illuminate many specific dilemmas. Trebilcock also pays close attention to how various theories may be translated into practice, revealing that ideas which appear to oppose each other at an abstract level are in fact similar when implemented at the institutional level. In conclusion, Trebilcock argues that we need to be more alert to the possibility of adopting public policies that broaden access to market opportunities for the disadvantaged. Economists, lawyers, political scientists, philosophers, and policy analysts will all benefit from reading this brilliant synthesis and reinterpretation of contract law.", "ISBN": "978-0-674-53430-8", "language": "en", "author": [{"family": "Trebilcock", "given": "Michael J."}], "issued": {"date-parts": [{"1997}]}, "locator": "96", "schema": "https://github.com/citation-style-language/schema/raw/master/csl-citation.json"}

1059 P. Akman, 'The Relationship between Economic Duress and Abuse of a Dominant Position' [2014] *Lloyd's Maritime and Commercial Law Quarterly* 99, 113.

1060 Id. 111. In this connection, Akman recalls Hovenkamp arguing that "[s]imple bilateral monopoly is not an antitrust problem because bilateral monopoly has no consequences for market prices and output" in Herbert Hovenkamp, 'Harvard, Chicago, and Transaction Cost Economics in Antitrust Analysis' (2010) 57 *The Antitrust Bulletin* 613, 14.

1061 P. Akman, 'The relationship between economic duress and abuse of a dominant position', (2014) *Lloyd's Maritime and Commercial Law Quarterly* 99, 102, who also noted that "the level of competition on a market and the objectionability of the contracts entered into on that market may be related" (Id., 101-102).

‘First, there is a danger that pure contract cases are litigated as competition cases, even where there is no harm to competition. [...] Secondly, competition cases can be litigated as contract cases. [...]’¹⁰⁶².

Adopting a separability thesis, which aims to establish clear boundaries for the application of competition law and contract law, Akman argues that ‘pure exploitative practices where there are no issues of exclusion are more appropriately dealt with by contract law rather than by competition law’¹⁰⁶³.

In conclusion, two views are usually advanced with regard to the interaction of provisions focusing on superior bargaining power and competition law. First, considerable effort has been spent in order to mould the concept of superior bargaining power into the competition law and economics traditional framework by bringing adjustments to traditional competition law concepts such as relevant market and market power¹⁰⁶⁴ or focusing competition law enforcement on ‘buying power’. Second, new provisions on superior bargaining power or economic dependence, introduced in the competition law statutes by some jurisdictions, are typically examined from the perspective of efficiency and consumer welfare and usually relegated to the outer boundaries of competition law provisions on abuse of a dominant position, for instance on the basis of an error cost analysis,¹⁰⁶⁵ or the perception that fairness concerns have little role to play in modern competition law¹⁰⁶⁶. Provisions on superior bargaining power are examined from a public choice perspective as a by-product of the political pressure of organised interests of small and medium undertakings or farmers, leading to the adoption of mainly redistributive statutes that restrict competition and presumably economic efficiency.

We consider that the ‘superior bargaining power’ concept is too easily dismissed by competition law scholarship. First, from a normative perspective, the role this concept may play in competition law enforcement becomes particularly significant, should one abandon a narrow neoclassical price theory (NPT) efficiency or consumer welfare driven perspective for an approach that would seek to preserve the competitive process or

1062 P. Akman, *The relationship between economic duress and abuse of a dominant position*, (2014) *Lloyd's Maritime and Commercial Law Quarterly* 99, 102-103.

1063 *Id.*, 108-109.

1064 See, for instance, § 20 of the German Act against Restraints of Competition on “relative and superior market power” (relative und absolute Marktmach).

1065 See, for instance, F. Wagner von Papp, *Unilateral conduct by non-dominant firms: a comparative reappraisal*, ASCOLA Tokyo Conference (2015), (on file with the author, shortly available at the SSRN) conducting an “error cost analysis” and advancing the view that dominance, and consequently the definition of a relevant market, is a necessary condition for a superior bargaining power to be considered as a competition law problem and recognising the countervailing impact that subsidiary contract law enforcement would have on error costs. An error cost analysis conducted in abstracto may underestimate the transaction costs associated with the use of the specific legal process, which may vary from jurisdiction to jurisdiction and in some cases may be less important in the context of competition law enforcement than other alternatives. Error cost analysis may also lead to the “sin of single institutional analysis” see, K. N. Komesar *Law's Limits*, (Cambridge: Cambridge University Press, 2001) as it will emphasize the defects of one institutional alternative (e.g. competition law) on some aspects to argue for an expansive role of another, probably equally defective in some other aspects, institutional choice: contract law or unfair competition law statutes.

1066 See, for instance, P. Akman, *The Concept of Abuse in EU Competition Law* (Hart Pub. 2012), Ch. 4.

even one that will be inspired by broader political economy considerations. Second, from a descriptive perspective, we note that legislators and competition authorities do not share the antitrust law pessimism usually displayed by authors inspired by the NPT paradigm towards the concept of superior bargaining power, and have increasingly engaged with it, in the context of traditional competition law enforcement with regard to retail consolidation through buying alliances or mergers, in particular in the context of vertical restraints. That said, we do not consider that the concept should dispense from an analysis, probably at a latter stage in the competition law assessment, of the existence of harm to competition as a result from the specific conduct, the simple exploitation of a situation of superior bargaining power not being equated to harm to competition¹⁰⁶⁷. The main added value of our approach is that it will not exclude outright from consideration exclusionary or exploitative conduct resulting from a situation of superior bargaining power, because of the simple fact that the undertaking in question does not dispose of substantial market power, defined as power over price (neoclassical market power), the latter concept functioning as a filter dispensing any further analysis. Such an approach will also break the artificial dichotomy between the step of determining the existence of a dominant position and that of identifying the abuse, thus enabling a more purposive definition of each element, enabling the claimant to put forward an overall theory of harm to competition resulting from the alleged abuse of a dominant position, which may eventually be rebutted by the defendant.

Recourse to the concept of 'superior bargaining power' may also expand the sources of market power taken into account in competition law. The attention of the competition law enforcers usually lingers on size and market share or concentration of the negotiating parties in order to define their power relations. However, scholarly studies on contracts and negotiations take a game/bargaining theory approach arguing that, for the outcome of negotiation, even more important than market shares or the size of negotiating parties is the existence of 'threat points' enabling one of the parties to seek a '*best alternative to a negotiated agreement*' (BATNA).¹⁰⁶⁸ Indeed, the negotiating party holding a BATNA has the possibility to resort to a valid alternative to the negotiation in progress or to the contract concluded, preventing hold-up and threats to cease negotiation. In conceiving the bargaining model one may take a Nash cooperative bargaining solution as the axiomatic starting point,¹⁰⁶⁹ or resort to a non-cooperative or sequential bargaining model which will attempt to factor in the costs of the delay to agreement, and extend this analysis from bilateral bargaining to n-person bargaining.¹⁰⁷⁰ Although

1067 With regard to this issue we agree with P. Akman, The relationship between economic duress and abuse of a dominant position, 130, who argues that 'demonstration of 'harm to competition' over and above harm to trading partners or competitors in all abuse cases may go some way in bringing clarity to the distinction between these two doctrines [economic duress and abuse of a dominant position]'.

1068 A. Renda and others, Study on the Legal Framework Covering Business-to-Business Unfair Trading Practices in the Retail Supply Chain, Final Report (2014) DG MARKT/2012/049/E 25, available at http://ec.europa.eu/internal_market/retail/docs/140711-study-utp-legal-framework_en.pdf; I. Ayres and B. J. Nalebuff, Common Knowledge as a Barrier to Negotiation (1996) 44 UCLA L. Rev. 1631.

1069 Most of these studies have relied on this type of model so far.

1070 See, for instance, J. Sutton, Non-Cooperative Bargaining Theory: An Introduction, (1986) LIII Review of Economic Studies

it is not clear if the results will be the same under each of these models, their common feature, in contrast to industrial organization theory, is that bargaining power is perceived as a concept that can be measured with reference to a specific bargaining relation in a specific context and it is not dependent on structural analysis (for instance the existence of monopsony or oligopsony). Bargaining power may also impact on price as well as on non-price terms.¹⁰⁷¹ Measuring bargaining power may be considered as a difficult exercise, although not necessarily more complex than that of measuring market power. It is encouraging that some competition law enforcers have tried to engage with the measurement task, adopting diverse approaches.¹⁰⁷²

The issue may take more centre-stage as in the modern digital and algorithmic economy, we observe very different processing and evaluation capabilities among firms, as a number of economic actors may be considered as holding “asymmetrical bargaining power” vis-à-vis their suppliers or buyers, through the collection of Big Data and the use of algorithms¹⁰⁷³. Some authors have even coined the term of ‘algorithmic power’¹⁰⁷⁴ in order to convey an additional, quite important, source of market power, in the sense that this is based on the ‘technological dependence’¹⁰⁷⁵ of economic actors that work and consume in an increasingly complex computational environment. It is also based on the capability of some actors to control the ‘agenda’ of decision-making¹⁰⁷⁶, for instance through the gate-keeping role of their digital platforms as the most important gateway of businesses to consumers¹⁰⁷⁷, or for the storage and processing of data¹⁰⁷⁸, the ‘oil’ of

the new economy¹⁰⁷⁹, or for the provision of artificial intelligence services. This is exemplified by, for instance, control over the choice architecture which frames individual choice in the context of an economic transaction. These economic actors will therefore be in a position to exploit their superior ‘algorithmic power’ and/or ‘manipulate’ the choice and eventually the preferences of their suppliers and buyers¹⁰⁸⁰. This may also be considered as forming a separate dimension of economic power for which specific metrics and methodologies need to be developed.

Developing appropriate metrics for measuring superior bargaining power constitutes one of the challenges to which competition law authorities that would like to integrate this concept in the competition law framework may face.

Attempts to measure bargaining power have so far focused particularly on the demand side bargaining power. Buyer power must not be conflated with monopsony and can take a variety of forms. Carstensen contends that “[t]he continuum of buyer power is a function of the following factors:

- (1) the buyer’s market options for its output;
- (2) the producer’s ease of switching outlets or product lines;
- (3) the quantities that the buyer takes from any one producer as a percentage of its purchases of that input; and
- (4) the percentage of its own output that a producer sells to a single buyer.”¹⁰⁸¹

In its report on the supply of groceries, the UK Competition Commission investigated the degree of buyer power of grocery retailers vis-à-vis suppliers. The Commission tries to define “buyer power” tautologically as being able to “obtain a better deal from its suppliers in terms of prices, product quality or purchasing terms, for example, compared

1081 Peter C. Carstensen, Competition Policy and the Control of Buyer Power. A Global Issue (Edward Elgar 2017), ch. 3.

with grocery retailers that do not have buyer power". In its assessment of the grocery sector, the possession of buyer power by grocery retailers is assessed by looking at four types of evidence:

- (1) the relative size of grocery retailers compared to suppliers;
- (2) the prices and margins that suppliers are able to negotiate with grocery retailers;
- (3) the share of the retail price that is earned by grocery retailers and others; and
- (4) a review of e-mail correspondence between two retailers and their suppliers, including e.g. evidence of below-cost selling by suppliers that would be difficult to explain in the absence of retailer buyer power.

In Japan, abuse of a superior bargaining position is prohibited by the Antimonopoly Act.¹⁰⁸² In its Guidelines Concerning Abuse of Superior Bargaining Position under the Antimonopoly Act, the Japan Fair Trade Commission defines a superior bargaining position as follows. Party A has a superior bargaining position over Party B in the following situation: (1) Party A makes a request that is substantially disadvantageous for Party B, and (2) Party B would be unable to avoid accepting such a request on the grounds that Party B has difficulty in continuing the transaction with Party A and thereby Party B's business management would be substantially impeded.

The existence of a superior bargaining position is determined by considering four sets of facts, taking into account both structural and non-structural factors:

1. The degree of dependence by Party B on the transactions with Party A, which if Party B is the supplier is measured with reference to the amount of sales by Party B to Party A, divided by Party B's total amount of sales;
2. The structural market position of Party A, i.e. its market share and ranking;
3. The possibility of Party B to change its business by starting or increasing its transactions with another party other than Party A, for instance based on Party B's specific investments for its transactions with Party A;
4. Other factors indicating the need for Party B to carry out transactions with Party A, including for example the amount of transactions with Party A and the relative business size of Party A.¹⁰⁸³

In 2014, the German Bundeskartellamt concluded an in-depth study in the food retail sector, where it attempted to measure superior bargaining power ("demand side power" – "*Nachfragemacht*") econometrically by exploring the conditions of its existence.¹⁰⁸⁴ The

¹⁰⁸² Article 2 (9)(v) of the Act on Prohibition of Private Monopolization and Maintenance of Fair Trade.

¹⁰⁸³ Japan Fair Trade Commission, Guidelines Concerning Abuse of Superior Bargaining Position under the Antimonopoly Act (30 November 2010), p. 5-6, available at http://www.jftc.go.jp/en/legislation_gls/imonopoly_guidelines.files/101130GL.pdf.

¹⁰⁸⁴ Bundeskartellamt, Sektoruntersuchung Nachfragemacht Im Lebensmitteleinzelhandel (2014) B2-15/11 BKartA, available at http://www.bundeskartellamt.de/Sektoruntersuchung_LEH.pdf?__blob=publicationFile&v=7 (hereinafter

conditions of bargaining power were converted into independent variables used for the econometric assessment. The selection of the independent variables was performed on the basis of a survey. In particular, the Bundeskartellamt looked into the procurement market of branded products for several reasons, including the fact that they form the core business of retailers, they are at the center of the majority of competition complaints and they are easier to compare and identify.¹⁰⁸⁵ The authority initially divided the products object of negotiations into four categories: “product category,” “must-stock items,” “items listed at a discounter” and “high-turnover items.” Furthermore, they identified seven procurement markets with different market structures. In order to identify and order the branded products forming the statistical population belonging to the sample, the authority used the European Article Number (EAN). The authority then interviewed the retailers and manufacturers about the results of their negotiations on each EAN article. In particular, the Bundeskartellamt inquired about the switching possibilities to alternative negotiating partners and about the overall competitive environment. The authority noted that negotiations between producers and merchants take place once a year. In these negotiations producers and merchants bargain over the conditions for the business relationships of the following year. Yet, the Bundeskartellamt also acknowledged that the sole focus on procurement volumes is not sufficiently differentiated to provide valid conclusions for the definition and measurement of demand-side bargaining power. For its econometric assessment, the Bundeskartellamt considered different determinants in order to describe the individual bargaining position of each party and did not base itself only on market concentration and the existence of a monopoly or an oligopoly. The bargaining model construed on the basis of this theoretical approach can be summarized as following:

K [conditions of superior bargaining power] = $f(x \text{ [amount ordered]}; D^{1-6} \text{ [bargaining determinants, which indicates the “Drohpunkte” (threat points), that is, the best alternative to negotiate]})$ ¹⁰⁸⁶.

These are the following:

- Alternative distribution paths for producer p (other than with retailer r) or even alternative production paths (switching to different product) = outside options of producer;¹⁰⁸⁷

Bundeskartellamt Food Retail Report)

1085 The other market identified by the Bundeskartellamt is the one of private labels, which the authority describes as characterized by a different “bargaining logic,” although deeply influencing the negotiations for branded products. Private labels are usually bargained through tenders, while branded products are traded with annual negotiations. However, in its econometric study the Bundeskartellamt states that “private labels are actually considered in the assessment of the “competitive environment” of the branded products,” see Bundeskartellamt, Summary of the Final Report of the Sector Inquiry into the Food Retail Sector, 8. In this connection the Bundeskartellamt observes that private labels are often considered as part of a different market with respect to branded products. However, they can be often used in negotiations to put pressure on manufacturers of branded products, at 11.

1086 Hence, the Bundeskartellamt especially focusses on the walk-away point in the specific negotiation and how it is influenced by different factors for each party.

1087 Bundeskartellamt Food Retail Report, 321.

- Outside options of retailer: importance of the product for the retailer (is delisting a credible threat?);¹⁰⁸⁸
- Brand strength: if consumers expect certain brands, then delisting is improbable;¹⁰⁸⁹
- Competition by other producers/brands which creates opportunities for r to circumvent p;¹⁰⁹⁰
- r's own brands ("*Handelsmarken*"): these must be substitutable for brands of p, and p must not be (by chance) the actual producer of r's own brands; the Report notes the trend towards private labels even in the premium segment;¹⁰⁹¹
- Buyer cooperation: bundling buying power¹⁰⁹².

The conditions adopted for this analysis were not only price terms but also non-price terms, such as deadline for payment and agreements on delivery. A fundamental stage of the Bundeskartellamt's assessment was the reckoning of the importance of a retailer for its suppliers and the evaluation of the "outside options" of both parties. The definition of "outside option" given by the authority resembles closely to the one of the BATNA, "*the better a party's outside options, the better the conditions that party is able to negotiate.*"¹⁰⁹³ Not surprisingly, the Bundeskartellamt concluded in this study that the purchasing volumes "*have a decisive impact on the negotiating conditions,*"¹⁰⁹⁴ and therefore constitute one of the main advantages of major retailers vis-à-vis their smaller competitors in negotiations. Furthermore, the authority determined that the well-known branded products "*the delisting of which would most likely result in a disproportionate decline in turnover for that retail company, has the effect that its manufacturer is able to achieve better conditions.*"¹⁰⁹⁵ In such cases, the producer is in a stronger bargaining position, since the retailer has no BATNA.¹⁰⁹⁶

1088 Bundeskartellamt Food Retail Report, 322.

1089 Bundeskartellamt Food Retail Report, 323.

1090 Bundeskartellamt Food Retail Report, 324. However the Bundeskartellamt states that this is only true if two conditions are assumed. Firstly the other brand has to pose a sufficient substitution to the article which is the subject of the negotiations and secondly that the producer of the relevant article is not also the producer of the alternative trade brand. The Bundeskartellamt measures the value of this influence with the help of a survey in which the undertakings were asked to assess the importance of alternative brands. Furthermore the survey asked for an assessment of the substitutability of the specific article through the alternative on a scale from 0% to 100 %..

1091 Bundeskartellamt Food Retail Report, 324-325.

1092 Membership in a buyer group reduces the outside-options of the supplier and thereby may lead to better conditions for the demand side. The impact of the membership is measured by adding a variable which is 1 for "yes" and 0 for "no". In a second step it is measured whether an undertaking is a "big" or a "small" member of such a group. Thereby a variable only gets the value one, when the undertaking is not the one with the highest turnover in the group.

1093 Bundeskartellamt, Summary of the Final Report of the Sector Inquiry into the Food Retail Sector, 10.

1094 Bundeskartellamt, Summary of the Final Report of the Sector Inquiry into the Food Retail Sector, 10.

1095 Bundeskartellamt, Summary of the Final Report of the Sector Inquiry into the Food Retail Sector, 10.

1096 However, these so-called "must-have" products accounted only to 6% of the sample adopted by the authority that, according to the same authority, can be reasonably taken as representative of the whole food-retail national market.

In a 2012 sector inquiry, the Italian Competition Authority studied the bargaining power of retailers and suppliers on the basis of three different “clusters” of undertakings, reaching comparable results.¹⁰⁹⁷ These “clusters” were obtained by comparing several data, including the overall turnover, the number of retailers supplied, the “strength” of the brand (especially in the specific geographic area). In particular, these three groups or “clusters” were: i) undertakings with high bargaining power; ii) undertakings with medium bargaining power and iii) undertakings with low bargaining power.¹⁰⁹⁸ The data published by the ICA relatively differs from that of the Bundeskartellamt, but still shows a situation of prevalence of retailers’ superior bargaining position, irrespective of market concentration levels. On the basis of their clusters, the ICA concluded that in the 23.4% of their sample, the supplier holds a strong bargaining position (not necessarily stronger than the retailer) and is not economically dependent on the retailer. In the 48.8% of cases, the suppliers showed an intermediate degree of dependence from the retailers. Finally, the 27.8% of the sample highlighted a high level of dependence.¹⁰⁹⁹

Both studies by the German and the Italian competition authorities engage with what may be considered as captive value chains in the GVC approach terminology and attempt to develop appropriate measurement tools for superior bargaining power that could be useful in also assessing vertical power (see Section X in this report).

4.5.3.4. Panopticon power

The power of specific nodes (actors) does not always result from the dependency of the other nodes of the network to which it forms part, for instance because of certain individual characteristics of this specific actor. Their influence may stem from their strategic position in the network. For instance, this position may enable them to extract an information advantage vis-à-vis potential adversaries, what Farrell and Newman call the ‘panopticon effect’ in reference to the institutional building and a system of control designed by English philosopher Jeremy Bentham¹¹⁰⁰. Panopticon power may emerge in situations where there is significant and growing learning-by-doing asymmetry between the actor benefitting from this position in the network and the other nodes in the network. In view of the importance of hubs in a decentralised communications structure, Farrell and Newman explain that ‘hub nodes can use this influence to obtain information passing through the hubs’¹¹⁰¹. These actors may therefore tap, because of their positioning in the network, into the information gathering and generating activities of the whole network, well beyond the nodes with which they have direct, or even indirect, relations. Hence, despite the function of such actors as simple intermediaries providing an infrastructure of communication, their influence can be quite significant. Panopticon power thus results from the position of an actor in a network and is not related as such

1101 *Ibid.*, 55.

to the existence of some form of dependence. It is possible that the different actors in a network voluntarily agree to share information through the hub, for instance because they trust it better than a direct communication between them, or because it is more convenient to do so. Although each of these nodes is not dependent on the hub, assuming that there are other available, and therefore in the context of their dyadic relation the hub does not have power, taking into account the fact that the actor also serves as a hub for a number of other interactions may provide that actor some superior and more complete information on the strategies of the other members of the network, including its adversaries, in case these have communication interactions with some of the nodes also communicating with the hub.

4.5.3.5. Architectural power

Competition fights are not only won through the use of traditional strategic competitive advantage, in terms of lower costs, higher quality products etc. Increasingly, firms engage with the overall structure, economic and legal, of the industry in which they are active seeking opportunities to frame their architecture in a way that favors their position. This quest for architectural advantage, which is particularly important in competitive fights in the context of ecosystems, hints to a different dimension of economic power, not usually taken into account by the traditional competition law metrics, architectural power. To the extent that this architectural power emanated from the central positioning of platforms in ecosystems, it has also been referred to as ‘positional’ power. This does not necessarily relate only to the position of an undertaking as an indispensable intermediary, although this may constitute a source of architectural advantage, but relates to the overall position of centrality of the platform or specific undertaking in the industry architecture. We will briefly explore the concepts of industry architecture and architectural power, before making some comments on the possible metrics that may be employed to assess it.

In addition to competitive strategies that engage directly with the actual and potential sources of competition, a firm may also acquire a durable competitive advantage if it holds a position that enables it to reshape the ‘industry architecture’ in its own advantage. The concept of ‘industry architecture’ follows David Teece’s seminal contribution on how profits from innovation and how the various governance arrangements between the innovator and other vertically-related firms may influence the distribution of these innovation gains¹¹⁰². Teece suggested a theoretical framework. First, it focuses on the co-specialization of firms so that their assets are tailored to each other and the firms develop a high degree of complementarity, as the combination of assets yields a higher value. Second, it focuses on ‘factor mobility’, which relates to the ability of a firm to appropriate value without necessarily owning the complementary asset. Teece focused on the dyadic relation between the innovator and outside asset holders finding that complementarity usually leads to lower factor mobility. However, more recently,

1102 David Teece, “Profiting from Technological Innovation: Implications for Integration, Collaboration, Licensing and Public Policy”, (1986) 15(6) Research Policy, 285.

Michael Jacobides et al. disentangled the two constituent components of co-specialization by finding that a firm may manage to “obtain *both* high complementarity *and* high mobility in their vertically adjacent segments”, which led him to expand Teece’s analytical framework beyond ‘dyadic relations’ to also cover the ‘industry architecture’, which is “the various templates circumscribing the division of labor among co-specialised firms at the level of an industry, or economic sector”¹¹⁰³. According to Jacobides et al.,

“(t)he concept of industry architecture (‘IA’) describes how labor is typically organized and structured within an industry (‘who does what’) and which firms capture value and profit as a result (‘who takes what’). It encompasses features such as the degree of vertical integration, the division of labor between firms and the ‘rules and roles’ that determine how firms interact and the business models, available to them. While IA reflects the conditions under which firms operate, it is influenced, in the medium term, by firms’ attempts to reshape those conditions to their own advantage”¹¹⁰⁴.

As Jacobides further explains, “(a)rchitectures provide the contours and framework within which actors interact: they are usually partly designed (e.g. by regulation or *de facto*, by standards), and partly emergent (by the creation of socially understood templates and means to coordinate economic activities)”¹¹⁰⁵.

Industry architecture is framed by the various economic actors at the birth of a new industry, the new players defining the interfaces (technological, institutional or social) that allow different entities to co-specialize and divide labor¹¹⁰⁶. As the industry progressively matures, we observe the emergence of ‘winners’ who strive to frame the industry architecture in their own advantage by developing complex strategies. The objective of these strategies is to capture a disproportionate amount of the surplus value created by the innovation.

Industry architectures are not meant to last forever, although they tend to be relatively stable for some time once the technology has sufficiently diffused. There are various reasons for this stability, such as the requirement for any new technology to be interoperable with the technical standards of the industry architect who benefits from an installed base, the quality certification barrier from which the technologies of the industry architect benefit, to the extent that consumers’ expectations have been framed according to the industry architect’s quality standard, the favorable legal framework from which the industry architect benefits as it may have been framed so to respond to the risks generated by the technology of the incumbent or to accommodate the needs of the industry architect. However, as Jacobides et al. observe, “(i)ndustry architectures

1106 Ibid.,

can...also change whenever new ways are found to put together the various industry participants: legal innovations that alter transaction costs..., new ways of safeguarding against loss from transactional hazards..., and technical innovations that alter the payoff to bundling specialized production factors...could inspire adjustment of an industry's architecture"¹¹⁰⁷. This shift from the dyad to industry-wide networks of relationships regarding the allocation of the financial returns of innovation also explains the reason for the competitive game being more complex and wider than the usual focus of competition law on a relevant market.

Various factors may influence industry architecture. One is technological path dependence which results from a self-reinforcing process triggered by an event, such as a first mover advantage leading to the choice of a widely used technology standard, which leads to a 'lock-in' to a less optimal, from a quality of technology perspective, equilibrium, without that being the intention of the agents at the first place¹¹⁰⁸. The legal/ regulatory framework may also play a crucial role in the definition of the boundaries of an industry and of its governance. Quite often it supports the existing industry architecture. Finally, path dependence and 'lock-in' may result from intentional strategies seeking to manipulate the industry architecture so to create a bottleneck. This is a segment of the value chain where there is limited mobility¹¹⁰⁹. The firm controlling the bottleneck is in a position to extract all surplus value in the specific segment as well as a higher percentage of the surplus generated by innovation in vertically adjacent segments¹¹¹⁰. This may take different forms, such as manipulating the setting of technology standards as often standards shape industry architecture or influencing the regulators and/or the legislative framework shaping the architecture of the industry, either directly through lobbying activity and pressure groups or indirectly by developing a narrative that will catch the imagination of policy-makers and legislators so that the emergent regulatory framework serves the interests of industry architect.

In conclusion, being in a position to influence the way the industry is organized or structured and the value allocation between the industry (or ecosystem) actors, provides 'architectural advantage'¹¹¹¹. This may be a quite important source of sustainable abnormal profits. This is probably the reason why 'architectural fights'¹¹¹² have characterized the evolution of all industries. The competition to become the industry architect plays a crucial role in periods of profound technological transformation, such as the development of new GPTs; in periods when new technologies that confer significant advantages, such as reducing costs or increasing productivity are progressively integrated in

¹¹⁰⁷ Ibid, fn 3.

¹¹¹¹ Ibid, 1200.

¹¹¹² Ibid, fn 13.

the production process in the context of a specific industry¹¹¹³. These technologies offer a higher rate of return on investment and often attract capital from other industries. In the context of the inter-industry competition that is one of the characteristics of financial capitalism¹¹¹⁴. The important role of financial markets in the development of the digital economy and the monetization of digital inputs also shifts attention away from the traditional focus of competition law on competition within an industry, to competition between industries, capital (in the sense of value-enhancing activity, which does not constitute labor) moving from one industry to another in search of higher profits. The concept of 'ecosystem' offers an additional space where intra- and inter-industry competition occurs.

According to the architectural advantage approach, the boundaries of an industry should not be considered as a given. Firms with superior performance (due to superior resources and capabilities¹¹¹⁵) aim to shape 'industry architectures' in a way that provides them control of a 'bottleneck', i.e. that would enable them to leverage their position of strength over all other companies that collaborate with them in the creation of surplus value¹¹¹⁶. Hence, to understand this process of value extraction that motivates strategies of competition, it is important to analyze the market level and the industry and eco-system levels. It also challenges the idea that there are cycles in the life of an industry: an industry being marked by a dominant design, with an established hierarchy and stable market shares that slowly erodes as the industry matures with product innovation mainly occurring through new entry. According to this view, the competition of capabilities takes place not only at market or segment level (e.g. among mobile handset manufacturers) but also at the value-chain level (e.g. among mobile handset manufacturers, network providers, content providers etc.). Contrary to (industrial) economics, which assumes that "(f)irms compete only within a market, and it is their performance, within that market, relative to other firms, that determines their profitability", the architectural advantage perspective focuses on the role of vertical competition and the way this affects the relative proportion of value (i.e. the 'NPV of future profits') that each segment captures, which may lead to important value shifts from one part of the value chain to another. The firms acquiring architectural advantage (the 'kingpins') take a central role in the overall industry architecture, influencing not only the segment they belong to but also multiple segments within a single industry or ecosystem¹¹¹⁷.

However, acquiring a bottleneck is not the only way architectural advantage converts to abnormal profits. Focusing on the appropriation of value from other value chain participants makes sense if one conceptualizes competition (horizontal or vertical) as essentially a process taking place on product or technology markets or eco-systems and

focusing on capturing value through the protection and/or leveraging of innovation. However, value may also be created by “investing in assets that will appreciate”¹¹¹⁸ and will, thus, increase the market value of the firm from the perspective of financial markets. Jacobides et al. note how this “subtle shift of mindset from profit (and isolating mechanisms) to wealth creation (and the potential for asset appreciation)”, explains why an industry architect may favor imitation by competitors, even if this reduces profitability, provided this strategy of openness increases the value of the underlying assets¹¹¹⁹.

4.6. Digital value chains as a new mapping tool in competition law: concept and metrics

A tool aiming to map the inter-firm networks on a global scale, the Global Value Chain (GVC) approach may also apply to explore a number of factors that may influence competitive interactions in the digital economy. We will refer to this specific application of the GVC approach as Digital Value Chains. Although the GVC tool was initially framed with the aim to assist policy-makers to design industrial strategies geared towards a greater participation of firms, active in their jurisdiction, to the global economy, its descriptive potential is wider. By exploring the sequences of tangible and intangible value adding activities, “from conception and production to end use”, GVC analysis offers a picture of global value creation and extraction both “from the top-down”, by examining for instance “how ‘lead firms’ govern their global-scale affiliate and supplier networks”, but also from “the bottom-up”, asking “how these business decisions affect the trajectory of economic and social ‘upgrading’ or ‘downgrading’ in specific countries”¹¹²⁰. We consider that the value chain approach may provide a quite useful tool in order to map horizontal and vertical competition in the context of the rapidly evolving digital economy, where various industrial structures begin to overlap. This process of convergence challenges the traditional definition of an industry by Michael Porter as ‘a group of companies offering products or services that are close substitutes for each other, that is, products or services that satisfy the same basic customers’ needs’ and the emphasis put on industry borders that, it is often assumed, have already been drawn¹¹²¹. Although it has long been accepted that the concept of industry is not useful, as ‘(q)uestions relating to competition, monopoly and oligopoly must be considered in terms of markets’¹¹²², in the fast moving world of digital competition who is a competitor, an existing firm or potential competition is often quite difficult to determine. For this reason, and in or-

1122 J. Robinson, *The Industry and the Market*, (1956) 66(262) *The Economic Journal* 360, 361. See also, E. Chamberlin, *product Heterogeneity and Public Policy*, (1950) 40 *American Economic Review* (Papers & Proceedings) 85, 86-87 noting that “(i)ndustry’ or ‘commodity’ boundaries are a snare and a delusion – in the highest degree arbitrarily drawn, and wherever drawn, establishing at once wholly false implications both as to competition of substitutes within their limits, which supposedly stops at their borders, and as to the possibility of ruling on the presence or absence of oligopolistic forces by the simple device of counting the number of producers included”.

der to map the complexity of the digital economy, and the various feedback loops in operation, it becomes essential to have recourse to new mapping tools, such as global value chains. These tools do not only serve the purpose of a better visualisation of the processes of horizontal and vertical competition. They also enable to better assess the bargaining asymmetries across the various segments of the value chain that may result either from the lack of competition on the markets affected or from the central position of some actors in the specific network and their positioning in the value chain. This tool may complete the market definition tool and brings to the centre of competition law enforcement the various dimensions of vertical (non-structural) power. We conclude with some suggestions as to the development of adequate metrics for vertical power, which if found to exist may trigger a more thorough competition law assessment of the specific business conduct.

4.6.1. Digital Value Chains as a new mapping tool

This mapping approach examines various dimensions: (i) the input-output structure of a GVC, by focusing on the process of transformation of raw materials and factors of inputs of production to final products, (ii) the geographic scope of GVCs which explains the degree of global dispersion of the chain, (iii) the governance structure of the GVC, which delves into the issue of control of the chain, (iv) the upgrading, which describes “the dynamic movement within the value chain” and “how producers shift between different stages of the chain”, their aim being to move to higher added value activities, (v) the local (or global) institutional context in which the value chain is embedded, including regulation and self-regulation, (vi) industry stakeholders that may be various local (but also global) actors of the value chain that interact to achieve upgrading. These may not only be companies, but also industry associations, workers, educational or research institutions, government agencies and ministerial departments. All these actors are involved to a certain degree in the operation of the global value chains and influence their development.

The framework shares Michael Porter’s emphasis on “*value systems*” a concept that has been used in order to describe a set of inter-firm linkages through which different economic actors (and their value chains) are interconnected.¹¹²³ GVC’s “holistic view” of global industries focuses on the governance of the value chain, that is, how some actors can shape the distribution of profits and risks in the chain. Taking a political economy perspective, the GVC approach explores the way economic actors may maintain or improve (“upgrade”) their position in the global value chain, “*economic upgrading*” being defined as “*the process by which economic actors—firms and workers— move from low-value to relatively high-value activities in GVC.*”¹¹²⁴ There are different types of upgrading: some relate to the entry in the value chain, where firms participate for the first time in national, regional or global value chains, others to “end-market upgrading”, firms moving into more

sophisticated markets that require compliance with new, more rigorous quality standards, or into larger markets that call for important investments in production scale¹¹²⁵.

The tool has been increasingly used by competition authorities, in the context of market investigation references or sector enquiries¹¹²⁶. The Furman report also recommended the completion of a market study by the CMA on the entire value chain of digital advertising (see Figure 4.20.). However, the tool has not been systematically used in infringement cases, most likely because of the emphasis put on horizontal competition and not vertical competition.

The smartphone industry also provides an interesting area for value chain analysis. The following account shows an evolving connection between the physical and digital aspects of value chains; this connection has followed the transition from basic mobile phones to smartphones¹¹²⁷. Prior iterations of this value chain show a preference for a number of more or less vertically-integrated undertakings, including the design and assembly of the final product as well the software implementation.¹¹²⁸

The dissection of the smartphone value chain into its segments is facilitated by loosely following a hardware/software division. This mirrors a 'solution stack' approach, which comprises of hardware (ie smartphone sub-components), device (the end-user machine), software (the operating system and other capabilities), services (cloud storage, navigation, etc) and content (apps). (see Figure 4.21.)¹¹²⁹

Figure 1: Example of a value chain (simplified)

Source: Author's compilation

For the present illustrative purposes, the smartphone value chain will be considered on the basis of three segments: smartphone manufacturing/assembly, software development, and distribution and network connectivity.¹¹³⁰

The first segment, smartphone manufacturing and assembly, involves firms that are involved in the physical creation of the smartphone. Different value chains and ecosys-

tems intersect this segment, involving for example the sourcing of the necessary input materials, or the production of certain hardware parts such as integrated circuits, memory chips, semiconductors, and cameras.¹¹³¹ In terms of components suppliers, there are some important players that affect this segment as a whole, including Qualcomm, Samsung Electronics, Intel, Texas Instruments.¹¹³²

The manufacture process proper involves a number of players, such as lead-firms (including two prominent companies like Samsung and Apple),¹¹³³ electronic manufacturing services (EMS) firms (such as Foxconn and Flex), and original design manufacturers (ODM) firms.¹¹³⁴ Although once focused on building their own devices, lead-firms started outsourcing this part of the process to EMSs and ODMs,¹¹³⁵ providing instead “market knowledge, intellectual property” including a strong, reputable brand.¹¹³⁶ On the other hand, EMSs and ODMs have also developed capabilities beyond assembly into component manufacturing and design of devices.¹¹³⁷ Different lead-firms have emerged in order to cater for different consumers, offering low-cost solutions or adopting online-only retail channels (as seen in Xiaomi).¹¹³⁸

The second segment of the value chain is software development. Firms that affect this segment can be subdivided in three categories, according to whether they provide a smartphone operating system, standalone software, applications (apps) and their marketplaces.

Operating system (OS) firms deliver a core foundational technology at the base of the functionality of smartphone devices. Some of the crucial players in this category include Apple with its iOS and Google with Android.¹¹³⁹ There are some differences in the business models of OS firms¹¹⁴⁰:

- Manufacturer-built proprietary OSs are designed by developers who are also the lead-firm (Apple’s iOS and the BlackBerry OS);

1140 Commission Staff Working Document, *Online Platforms SWD(2016) 172 final*, 24.

- Third-party proprietary OSs are designed by developers who license the OS, usually for a fee, to third-party hardware manufacturers (Microsoft's Windows OS);
- Open source Oss are designed by developers who release the OS via the open source license method (for eg Google Android).

In practice, the choice of whether to exploit the operating system has impacted other companies. Amazon and Xiaomi, for instance, have used open-source Android to build their own proprietary system above it, thereby adding an element of complexity to the operating system category.¹¹⁴¹

Firms in the standalone software category provide software that is deemed necessary in smartphones. In the past, in particular, smartphone devices included such software as Adobe Systems' Acrobat Reader.¹¹⁴²

Another important category of firms in this segment includes apps and their online marketplaces. An app is defined as a "standardised piece of software that runs on a computing platform,"¹¹⁴³ that is provided over the internet and through centralised online marketplaces.¹¹⁴⁴ Thus, apps are surrounded by a whole ecosystem of actors such as developers and network operators, each playing an important role. Network operators, for example, may preload a particular app marketplace on models of smartphones they sell.¹¹⁴⁵ Apps marketplaces, (including the likes of App Store, Google Play, or Windows Phone Store) vary in terms of their exclusivity to a particular operating system and revenue models. Users of Apple and Windows, for example, need to get their app content through the dedicated marketplace; conversely users of Google can use the official Google Play as well as other important marketplaces (Amazon, Xiaomi, GetJar).¹¹⁴⁶ Certain app marketplaces are also offering apps, designed in the latest markup languages to present content, in order to be more "OS-agnostic" and fit in different operating systems.¹¹⁴⁷ In terms of revenue, a number of apps marketplaces (such as Google Play and App Store) adopt a revenue-sharing model, whereby a share ca. 70% is normally passed to developers.¹¹⁴⁸

The third segment of the value chain is distribution and network connectivity. The principal firms in this segment are network operators, who have the double function of distribution/sale of smartphone devices as well as operating their connectivity to the

infrastructural network.¹¹⁴⁹

The first function is illustrated by the combination of subsidisation of smartphones devices, customer locked SIM cards, and device exclusivity.¹¹⁵⁰ The subsidisation is then recouped through a contract that provides for a monthly subscription fee.¹¹⁵¹ The second function, instead, does not include only voice and message services but also connectivity for the delivery and support of apps, which in turn rely on a stable and reliable service.¹¹⁵² The network operators that also control the network infrastructure are entrusted with the management and prioritisation of streams of data – an issue that has been flagged as raising potential network neutrality considerations.¹¹⁵³ Companies that operate in this segment include established players (such as Telefonica, TMobile, Verizon Wireless, China Mobile) as well as more recent entrants, including MVNOs and other companies (like Google) who have made investments in wireless and fibre optic cable.¹¹⁵⁴

The issue of value extraction in the smartphone value chain is multifaceted, with many aspects and recent developments that have somewhat confused the picture.

In terms of the smartphone manufacture/assembly, lead-firms tend to extract a greater share as they control intellectual property, design, branding and all other high-value aspects.¹¹⁵⁵ This is to the detriment of contract manufacturers or outsourcing companies that merely provide assembly.¹¹⁵⁶ However, two relevant trends have emerged in recent times that may contradict this illustration. First, convergence in handsets design and specifications could mean that outside of the top-two lead-firms (Apple and Samsung), competing companies could struggle in extracting higher shares, particularly if they are

“hardware-centric.”¹¹⁵⁷ Secondly, contract manufacture companies have moved to extract greater value through vertical integration, by specialising in component manufacturing and higher-value elements such as design; an instance of this is Foxconn that now provides an array of services to a significant number of lead-firms.¹¹⁵⁸

One solution that some firms in this segment have adopted to recapture value is the operation of a “hardware-software unit”. Although not universally accepted (as seen by Google’s sale of Motorola Mobility after acquiring it three years prior)¹¹⁵⁹ this solution suggests an important consideration: understanding how value is distributed requires the adoption of a multi-segment view of the value chain.

Platforms (like Microsoft, Google, and Apple) have managed to operate as multi-sides markets, extracting value by developing ecosystems that span across device, operating system and app marketplace, and thereby attracting “a range of complementors such as app developers, network operators, and device manufacturers.”¹¹⁶⁰ The control of these different elements has given platforms the flexibility to use them in the way they see most advantageous, locking-in firms in the various segments of the value chain, and benefiting from a mix of direct and indirect network effects as well as single-homing.¹¹⁶¹ In practice, one can see the realization of this strategy by looking at two diverging models.

On one side, Apple has opted to retain full control over the value chain, including hardware components, design, OS, app store, apps and “associated services (music, books, maps, mail, calendar, cloud storage, messaging, video calls).”¹¹⁶²

On the other side, Google has adopted an open-source, freely licensed model in respect of the Android OS. This approach has made the Android operating system popular with many smartphone lead-firms, while giving control to Google with regards to device certification (Android Compatibility Program).¹¹⁶³ This in turn has hindered other operating system firms (Windows Phone, Firefox, Tizen, and Ubuntu)¹¹⁶⁴ by limiting their business model or access to smartphone devices. At the same time however, Google has man

aged to retain control of the Android APIs benefiting the proprietary version of Android, limiting the connectivity value of the fully open source Android.¹¹⁶⁵

In terms of how network operators extract value in the value chain, a number of factors have emerged in recent years. Network operators have had a key role in the distribution and sale of smartphone devices.¹¹⁶⁶ Moreover, network providers (especially those with connectivity infrastructure) have featured, to a greater or lesser extent, flexibility and control in managing data streams.¹¹⁶⁷

Nonetheless, exclusivity contracts between network operators and popular smartphone devices have also resulted in network operators handing over significant rates in revenue-sharing plans to platforms or smartphone lead-firms;¹¹⁶⁸ moreover there have been cases suggesting that exclusivity now features less in relation to leading smartphones.¹¹⁶⁹ On the connectivity side, emerging apps and consumer preferences for content over the Internet have resulted in less control by network operators over the service that is provided to users, and this has affected the revenue streams of these companies.¹¹⁷⁰

Finally, one should note how Google and Apple may also have a greater impact on the role and value-extraction by network operators. Google has invested in connectivity infrastructure, perhaps with a view to decrease reliance on 3rd party networks,¹¹⁷¹ and both companies have individually invested on innovations that allow customers greater mobile network flexibility such as MVNO Project Fi (in the case of Google) and Apple SIM.¹¹⁷²

M&A transactions in the smartphone value chain have provided consolidation in some segments more than others. In respect of smartphone manufacture and assembly, some of the noteworthy acquisitions include Google's acquisition of Motorola, then sold to Lenovo.¹¹⁷³ Outside of such transactions, there has been a high level of market con-

centration in the case of two top lead-firms (Samsung and Apple), coupled however with dynamic and innovative smaller competitors (as Huawei, Oppo).¹¹⁷⁴ The consolidation of lead-firms has in turn resulted in the consolidation for the other companies that supply them with important services, such as EMS and ODM.¹¹⁷⁵

In the segment of distribution and network connectivity, one can also see a trend towards consolidation, particularly on a more national geographical level.¹¹⁷⁶ Examples of this include the acquisition by Three of O2 in Ireland, and that by O2 of E-Plus in Germany, both resulting in the decrease of significant wholesale network operators in those countries.¹¹⁷⁷ Furthermore, there have been transactions involving fixed and mobile operators, including the purchase by Liberty Global of Base in Belgium.¹¹⁷⁸

Data-driven business models feature strongly in some segments of the smartphone value chain. Big Data drives revenue streams connected to advertising through a number of different channels, including engine search, display ads and in-app advertising.¹¹⁷⁹ An interesting example is Google, which offsets any costs of providing free access to Android by means of advertising revenue obtained, for instance, in the Google Play app marketplace.¹¹⁸⁰ A similar approach, although different with regards to the availability of the operating system, is followed by Apple.¹¹⁸¹

Platforms operate as multi-sided markets that combine different smartphone services and engage collect data in order to create “robust user profiles.”¹¹⁸² For instance, the use of online marketplaces to download apps enables the storage of information on the types of apps downloaded, the smartphone, language and so forth.¹¹⁸³ Coordination and integration of the user’s profile is also assisted by provisions of other services, as shown by the interaction of Google’s Gmail, Maps, Drive and Wallet.¹¹⁸⁴

Network operators can also potentially build user profiles, through billing information and data, provided that smartphone transactions are managed directly by network op-

erator rather than other intermediaries.¹¹⁸⁵ Purchasing, billing and other consumer behaviour data is also used by companies in other segments of the smartphone value chain, like of Amazon, where they can integrate user's profiles with their proprietary technological innovations (such as recommendation engine).¹¹⁸⁶

4.6.2. Vertical power: metrics

As we have already explained in Section 4.5.3., there have been many different names to refer to vertical power, perhaps because of disagreements as to how the different dimensions of vertical power may be integrated in competition law assessment, there has been paucity of systematic research on metrics of vertical power. This becomes particularly important in the context of the digital economy, and in particular in order to decide in which instances to trigger competition law intervention for conduct adopted by digital platforms that harms their suppliers, or the members of their ecosystems, and which may also cause consumer harm, or other social costs, as the traditional filter and metrics of market power may only provide part of the picture and does not, as we have explained in Section 4.5.2., cover all instances in which vertical power may not be structural and still cause concern.

We regroup in Table 4.2., the different approaches of vertical power by reference to the theoretical framework that has led to the definition of the specific type of vertical power we examine. One should be cautious to infer any possible anticompetitive effects from such vertical power. We distinguish two steps in the analysis, the first concerns the existence and exercise of some form of vertical power and the development of a filter that may indicate that the issue may be worthy of further competition investigation, with regard to the possible strategies and outcomes, the second consists in assessing the likely outcomes and potential social costs of a specific practice that may result from the restriction of horizontal or vertical competition and/or of a restriction of inter-platform or intra-platform / intra-ecosystem competition.

Table 4.2.: Features of Vertical Power Theories

Power family	Type of power	Source of power	Modality of power exertion	Scope of power sourcing exertion	Existence of standard metrics or modelling
Pro-cess-based	Pro-cess-based	Capacity to apply credible sanctions that affect another agent's gains	Credible sanctions that affect another agent's gains	Vertical and horizontal	Yes

¹¹⁸⁵ *ibid.*

¹¹⁸⁶ *ibid.*

Power family	Type of power	Source of power	Modality of power exertion	Scope of power sourcing exertion	Existence of standard metrics or modelling
Resource dependence	Standard market power	Market structure	Affecting equilibrium quantities or prices in a market	Vertical and horizontal	Yes
Resource dependence	Exclusionary/bottleneck	Supply-side (e.g. an essential facility or input, a technology) and demand-side (e.g. high switching costs, strong positive network effects) conditions creating a bottleneck	Exclusion from the bottleneck resource	Vertical	Yes
Resource dependence	Social exchange theory	Differential dependency between value co-creators	Obtaining a high share of the co-created value through bargaining	Fully vertical	No
Positional	Panopticon	A position in the network of value co-creation that allows to collect valuable information	Strategic use of the information to obtain a higher share of value	Fully vertical	No
Positional	Architectural	Capacity to influence the industry architecture by affecting at least one of its interphases (technological, institutional, social)	Influencing the industry architecture to obtain a higher share of the value created in the industry	Fully vertical	No

Source: B. Carbala & I. Lianos, Vertical Power: Theory and Metrics (forth. CLES Research Paper Series, 2019)

We provide in Annex 3 different metrics for the specific types of vertical power we have examined in Section 4.5.3¹¹⁸⁷.

First, we provide a metric of resource-based vertical power based on differential dependency. These metrics correspond to situations of ‘resourced-based’ differential dependency (i.e. dependency not depending on ownership or market shares, but only on how essential the firm is to the value chain). We have developed the indicator at the firm and at the value chain level, as we consider that both levels are important for the competition assessment, in particular of practices limiting intra-platform and vertical competition.

¹¹⁸⁷ This research forms part of a large common project between Bruno Carbala and Ioannis Lianos on Vertical Power: Concept and Metrics. The thoughts shared in this Report are subject to further research and revision.

Second, we provide a metric of resource-based vertical power based on differential dependency, this time looking at what is often omitted by traditional competition law focusing on product markets, but which has to be incorporated in competition law if one takes financialisation seriously. We consider the ownership structure as a source of dependency within a value chain. As we explore in two different papers, the ownership structure may become a source of intra-value chain dependency¹¹⁸⁸.

Finally, we are working on a metric of panopticon power that engages with the type of concern that may arise out of structural holes and brokerage in the context of a more general “information-intensive” value chain.

4.7. A roadmap for the future

It results from the above that mainstream competition law may not always constitute an adequate tool to deal with the market failures that may digital markets present some of the characteristics of a natural monopoly, in particular the configuration of high fixed costs and low to zero marginal costs, and are often marked by strong network effects that lead to ‘winner takes most’ dynamics. In conjunction with learning by-doing effects and increasing returns to scale, network effects enable digital platforms to easily leverage their power across markets through different exclusionary strategies (e.g. making the technical standards of the platform incompatible with apps developed by competitors or with apps that may commoditise the platform, bundling and other pricing strategies, or non-price discrimination strategies that may raise rivals’ costs). The race to be a dominant firm in a network industry may increase the possibility of a lock-in to a technology which, when decisions taken in every period, looks optimal given past decisions, but is sub-optimal if decisions are delayed and all the decisions are taken at once. Hence, although the specific standard may appear efficient, from a static perspective, it may lack in dynamic efficiency.

Furthermore, in markets with strong network effects, once few firms are in operation, the addition of new competitors, even under free entry, does not change the market structure in any significant way. Although eliminating barriers to entry can encourage inter-platform competition, the resulting competition may not significantly affect market structure. Hence, it is possible that competition authorities may not be able to significantly affect market *structure* by eliminating barriers to entry.

One may face similar difficulties with regard to promoting intra-platform and/or vertical competition. The criticism often addressed to digital platforms¹¹⁸⁹, is that they seem to capture the most important part of the surplus value brought by digital innovation.

1188 See, I. Lianos, A. Velias, D. Katalevsky & G. Ovchinikov, Financialisation of the Global Food Value Chain: Implications for Competition Law, in I. Lianos, D. Davis & A. Ivanov (eds.) *Competition law and the Global Food Value Chain(s)*, (Cambridge University Press, *forthcoming 2019); B. Carbala & I. Lianos, Vertical power: concept and metrics (forth. CLES Research Paper 2019).

1189 See Australian Competition and Consumer Commission, *Digital Platforms Inquiry: Preliminary report* (Commonwealth of Australia 2018); Valerio de Stefano and Antonio, *European legal framework for “digital labour platforms”* (European Union 2018).

However, the current tools of competition law seem to only focus on horizontal competition rather than vertical competition and the distribution of surplus value, thus excluding vertical fairness issues from the competition assessment. The only vertical issue explored is that of the allocation of surplus between consumers and producers, but again in the traditional NPT approach this is perceived from the angle of Kaldor Hicks efficiency and is cause of concern only when it reduces the level and/or quality of output. There are different strategies one may adopt in order to promote intra-platform competition. Non-discrimination or neutrality enhancing policies, or policies against abusive termination from the platform may limit the risks of self-preferencing and foreclosure, while access duties to the parts of the platform that may be considered as 'essential facilities' could protect the ability of the platform's partners to develop competing offers (to those of the platform's subsidiaries) in the other segments of the digital value chain. One may also think of the constitution of institutions with countervailing powers, such as unions of Google users, trade unions representing gig self-employed, such as Netflix artists and Uber drivers, or cartels of media companies, which would have the possibility to collectively bargain with the digital platforms and tame their power. The role of competition law will be in this case not to jeopardise the development of these countervailing powers by exempting horizontal cooperation that has this purpose. Such an option may nevertheless backfire and produce important costs without having any assurance that could be outweighed by any potential benefits.

Hence, if the traditional competition law approach does not work, what are the other available options?

Utilities-style regulation: If we accept that competition may not work in these natural monopoly-like markets, would that be an argument in favour of adopting a pervasive utilities-like regulation? There are different options if the specific digital platform may be considered as a natural monopoly. First, allow the monopoly to maximize profits by producing at the monopoly level. This would however result in a deadweight loss (loss of consumer and producer surplus). Second, it is possible to require the monopoly to set its price where the average cost curve crosses the demand curve. This transfers some surplus from the monopoly to the consumers, expands output, increases social surplus, and reduces deadweight loss. Third, the natural monopoly may be required to set its price where the marginal cost curve crosses the demand curve. This eliminates deadweight loss but revenues no longer cover costs. As a result, tax money must be used to subsidize the production of the good. Finally, the natural monopoly may be obliged to charge a zero price. This also results in a deadweight loss and causes costs to exceed revenues, necessitating subsidies.

Some of the digital platforms may be considered as presenting the characteristics of a natural monopoly to the extent that entry into the industry requires high fixed costs and the industry also faces declining average costs, once the 'entry fee' (fixed costs of production) into the industry is paid. In natural monopolies, the quantity of the good can be produced at the lowest cost by having a single firm. In this context, the monopolist will reduce output, which will lead to deadweight loss. However, digital platforms are not

a natural monopoly like any other, as in contrast to natural monopolies in the utilities' sector, they do not face a declining marginal revenue when they grow their production. The reason for that is the important increasing returns to scale and learning-by-doing effects, in particular learning-by-doing by algorithms, as well as the incentives provided to them by their valuation by financial markets (financialisation) to grow eternally. The important thing to have in mind though here is the type of 'output' produced by some of these digital platforms. For matching platforms, the output can be determined as the number of matches effectuated (e.g. for dating platforms could be the number of dates, for search engines it would be the number of searches), but most of this 'output' is actually related to the facilitation of transactions. This may be considered as 'output' (transactional output) but again it is not clear how this intangible output may be factored in the framework of natural monopoly that has been merely developed in the context of the tangible economy. Platforms are not also producing data but harvesting data. Could data be considered as the output? If this is the case, one may wonder if there would be reason to value such increase in the harvesting of data, if this has negative effects on attention, a scarce resource, or produces externalities to other users (reducing their privacy) through the learning effects produced in terms of the platform being able to make more accurate prediction for users who have only consented to a limited harvesting of their data and for whom data may be largely unavailable. Hence, there may be reasons a policy maker might decide to control the exercise of socially undesirable market power by the natural monopoly.

How utilities-like regulation may work in practice for digital platforms? First, it might take the form of rate regulation. One may calculate the rate that would allow a digital platform to cover its total cost plus a fair rate of return on investments, or can impose a price-cap regulation and ceilings on the increase in prices over the 'money' side of the platform. Such 'rate' regulation may also work in the context of the subsidised side, as platforms may be required to offer positive prices to the users (eg. rewards), or eventually push the digital platforms to adopt a different business model (e.g. move from an advertised-base model to a subscription or royalties-based model)¹¹⁹⁰.

A second option is to choose non-price regulation in order to limit externalities resulting from the incentive of the digital platforms to grow (and thus increase their market valuation) by harvesting even more personal data, or capturing an even higher percentage of the attention of their users. It would be possible in these cases to limit their output, in terms of data harvested or attention-grabbing advertising. As Pigou explained, "(i)n an industry, where there is reason to believe that the free play of self-interest will cause an amount of resources to be invested different from the amount that is required in the best interest of the national dividend, there is a *prima facie* case for public intervention"¹¹⁹¹ One may possibly determine the socially optimal output (in the context of attention markets), for instance the number of ad-slots that should be available on a general

1190 This is possibly one of the implications of the remedies finally agreed in the recent Commission's decision concerning Google Shopping:

1191 A.C. Pigou. *The Economics of Welfare*, (Macmillan & Co., 1932), 331.

search page. However, this type of regulation may also face important difficulties, in particular in order to determine the appropriate rate of return for the digital platform. Of course, there is the theoretical possibility of replacing competition in the market with competition for the market, by enabling the government to auction off a monopoly franchise contract in order to deliver the functionalities provided by digital platforms¹¹⁹². The boundaries of the markets to be auctioned are nevertheless notoriously vague and rapidly evolving in the dynamic context of digitalisation. As Richard Posner also noted a few decades ago, even if governments make the choice of an auction, the incumbent will have a cost advantage and in reality the auction will be a re-negotiation with the incumbent¹¹⁹³. Historical experience teaches us that even if administered contracts (such as franchises) following an auction are the best solution, this often evolves towards full-fledged regulation¹¹⁹⁴.

Soft or light-touch regulation: Another option would be to adopt some light touch regulation of the way platforms organise their relations with the businesses that are part of their ecosystem, eventually by adopting a code of conduct for digital platform, or some more binding form of public regulation. This is the option put forward by the European Commission in the recently adopted *Platform to business regulation*, where a number of duties of non-discrimination and transparency were imposed to most digital platforms, irrespective from the fact they have, or not, market power¹¹⁹⁵. One may also refer to the recent proposals of the Furman Commission to impose to digital platforms with a 'strategic market status' to implement a code of conduct. This would result from a concerted effort of the digital platforms and unidentified "stakeholders", and would complement antitrust enforcement with a clearer and more easily applied set of standards defining the boundaries of undesirable conduct in digital markets¹¹⁹⁶. One may contrast this 'soft law' approach with the more 'hard law' implementation of the abuse of dominance or monopoly provisions in order to ensure that digital platforms do not limit intra-platform or vertical competition. The concept of intra-platform or intra-ecosystem competition refers to competition between the members of the same platform/ecosystem. This can be vertical (if the product markets are complementary) or horizontal as it is possible that a platform includes companies that are competing with each other in the same relevant product markets, or in the same geographic markets. Vertical competition does not refer to competition on relevant product markets but competition for capturing the surplus value.

1192 For a classic discussion, see H. Demsetz, *Why Regulate Utilities?*, (1968) 11 *Journal of Law & Economics* 55.

1193 R. Posner, *Natural Monopoly and its Regulation*, (1969) 21 *Stan. L. Rev.* 548.

1194 See, the discussion in G. L. Priest, *The Origins of Utility Regulation and the "Theories of Regulation" Debate*, (1993) 36 *J.L. & Econ.* 289.

1195 On February 13th, 2019, the European Parliament, the Council of the European Union and the European Commission reached a political deal on a Proposal for an EU Regulation on promoting fairness and transparency for business users of online intermediation services (April 2018), available at <https://ec.europa.eu/digital-single-market/en/news/regulation-promoting-fairness-and-transparency-business-users-online-intermediation-services>.

1196 Furman Report, 57-63. Designing a code of conduct has also been proposed by the Japanese competition authorities, see Japan Fair Trade Commission, *Interim Discussion Paper: Improvement of Trading Environment surrounding Digital Platforms* (December 2018), 6-8.

There are different reasons that may operate as justifications for such an approach. The one put forward by the recent European panel of experts Report is that (at least dominant) digital platforms ‘play a form of regulatory role as they determine the rules according to which their users, including consumers, business users and providers of complementary services, interact, and, when they are dominant, have a responsibility to ensure that competition on their platforms is fair, unbiased, and pro-users’¹¹⁹⁷. Hence, ‘to the extent that the platform performs a regulatory function, it should bear the burden of proving that self-preferencing has no long-run exclusionary effects on product markets’¹¹⁹⁸. As it is noted in the EU report, ‘(d)ominant platforms have “regulatory power” and have a responsibility to use that power in a pro-competitive manner’¹¹⁹⁹.

Property rights on data: One may also argue that we need to create the missing data markets by establishing property rights for data and providing each individual the possibility to transfer and sell this data. The recent GDPR data portability right provides an illustration of the introduction of some property rights’ logic, but of course one may push this further, for instance by treating the use of a search engine and the facilitation (active or passive) of data harvesting as a form of labour contributing to the surplus value generated by the digital value chain that has to be compensated¹²⁰⁰. The State could organise the process of commodification of human consciousness that will enable all citizens to at least benefit from some of the value generated by their data. Such an approach may increase the resources available for the less well-off who can now sell their own data and use them as collateral. However, this will not solve the problem of the structural inequality between those controlling these digital platforms and the rest of the population, in particular if the digital platforms do not face effective competition and consumers are unable to switch easily and port their data or other data-related inputs. Such an approach may receive the blessings of prioritarians who are ready to give priority to the less well-off instead of caring about equal distribution itself, but it would certainly be considered as problematic for egalitarians who put an intrinsic value on equality of distribution.

Natural resources regulation: Some jurisdictions take this propertization logic to the next level. For instance, the recent national e-commerce policy in India, proclaims that the data that is generated in India belongs to Indians as do the derivatives there from, It takes a natural resources view by claiming that

‘(t)he data of a country, therefore, is best thought of a collective resource, a national asset, that the government holds in trust, but rights to which can be permitted. The analogy of a mine of natural resource or spectrum works here” and that “India and its citizens have a sovereign right to their data’¹²⁰¹.

Using countervailing powers to tame the digital platforms: A light interventionism option, compared to the previous ones, is to accept that the structure of digital markets on which dominant platforms have emerged cannot be transformed to a more competitive structure, in view of the bottlenecks they control, and attempt instead to develop countervailing powers along the digital value chain that may tame the power of digital platforms and attempt to bargain a fairer allocation of the surplus value between the various segments of the digital value chain. This approach may be inspired by that put forward by US economist John Kenneth Galbraith who emphasised the role of countervailing powers in capitalism, being generally indifferent to concentrations of economic power, to the extent that government provides countervailing powers ‘freedom to develop and to determine how it may best do so’¹²⁰². Recent talk about enabling users, self-employed gig workers, or even media companies to collectively bargain with platforms mutually efficient solutions, by enabling them to cooperate without such cooperation falling under the scope of the prohibition of competition law to collusive activity constitutes an example of what is possible. One may also argue that the lack of antitrust enforcement in the US against Big Tech, in particular with regard to monopolisation, and the withdrawal of net neutrality regulation, may be read as advancing a *laissez-faire* programme, or may also be read as a way to engineer the emergence of countervailing powers along the digital value chain. Similar arguments have been made with regard to the development of countervailing powers that would thwart the power of digital platforms through code, such as the ability of consumers to outsource purchasing tasks to algorithms, thereby minimizing the direct role they play in purchasing decisions and overcoming biases ‘to enable more rational and sophisticated choices’¹²⁰³. However, it is unclear if a countervailing powers approach, that would anyway require a great degree of sophistication and prior design, may succeed.

Polycentric competition law: Another option would be to abandon the sole focus on consumer (or social) welfare for one that would aim to also promote *well-being* (consumers or that of the general public).¹²⁰⁴ Such an approach would seek to enhance the cognitive openness of competition law so that it can address the multilevel strategies to restrict competition that are expected to unfold in a complex economy, and to account for the diversity of values or orders of worth in productive friction in society by preserving and promoting spaces of polycentricity (or polyarchy).

Taking a social contract perspective, competition authorities should try to assess the broader social costs of market power. They should consider that the consumer is also a citizen that may value privacy and other public values (e.g. informational self-determination, protection of the environment and sustainability).¹²⁰⁵ By focusing almost exclusively on the price dimension competition law is monocentric and plays with a toy

1202 J. K. Galbraith, *American Capitalism: The Concept of Countervailing Power* (Mifflin Co. 1952): 143.

1203 M. S Gal & N. Elkin-Koren, ‘Algorithmic Consumers’ (2017) 30(2) *Harvard Journal of Law & Technology* 309

1204 We note a significant contrast with the Furman Report, which asserts ‘consumer welfare is the appropriate perspective to motivate competition policy and a completely new approach is not needed’. Furman Report (n 83), 5.

1205 See M. Novak, *The Spirit of Democratic Capitalism* (Simon & Schuster 1982), (differentiating society into three power centres: a political sector, an economic sector, and a moral-cultural sector).

economy that only exists in the economic textbooks. In other words, competition law should move from a monocentric vision focusing on prices and output to a polycentric vision that perceives competition law as an important tool in order to preserve the plurality and autonomy of the various social spheres that may be affected by the rise of digital platforms. Enforcing competition law in a complex economy setting would require the development of a deeper understanding of the social structure of competition and of the various spaces on which competition tournaments may take place.¹²⁰⁶ As it was previously explained, individuals interacting with data comptrollers in the context of an online market transaction are participating in overlapping games in the political sphere with the same corporations. Different methodologies should also be developed to account for this complex reality, such as agent-based modelling and sophisticated computation or the use of simulation techniques to better map the multi-functional strategies of actors in the various competition ecosystems and allow for computation.¹²⁰⁷

But more importantly, polycentric competition law aims to connect the activity of competition authorities with other regulatory fields, the relation between competition and regulation not being conceived as antagonistic but as complementary.¹²⁰⁸ Our brief analysis showed the relative poverty of mainstream competition law to deal with the variety of social costs engendered by the emergence of digital platforms as the dominant players in today's digital economy. It also showed how important it is to make efforts to understand that modern economies and societies are complex systems that may not be dealt with easily with the simple economics of modern competition law.

In our view, one therefore needs to take a **toolkit approach** that would combine different approaches and different areas of law and regulation, competition law playing a primordial role in this new regulatory compass. Actually, as constitutional law provides broader directions for regulatory and administrative action, competition law could play a similar role in terms of promoting the principle of competitive markets among other principles and values that need to be catered for. For instance, a lot of regulation, such as the Open Banking regulations in the UK, result from and integrate competition law values. One may also design property rights and data markets in a way that promotes the values of competitive markets in the economy as an autonomous sphere of justice.

This toolkit approach may rely on different combinations in each jurisdiction, on the basis of the institutional capabilities and the relative efficiency of the various regulatory alternatives, any choice being between imperfect, if perceived in isolation, institutional alternatives.

These considerations lead us to advance a different approach in exploring competition law in the digital era.

1206 R.S. Burt, *Structural Holes* (HUP 1992).

1207 See L. Hamill & N. Gilbert, *Agent-Based Modelling in Economics* (Wiley 2016).

1208 The complementarity between competition law and regulation is also noted in the European Commission's digital report and the Stigler Centre report. Crémer et al (n 203), 52-53; Stigler Report (n 707), 78.

- First, the complexity of the production process highlights the importance of conducting a careful analysis of the power relations *along* the digital value chain, and not only *between* different value chains, the aim being to unveil *value extraction bottlenecks* affecting the distribution of the total surplus value generated by digital innovation. The analysis cannot always be undertaken by the traditional NPT approach, which mainly focuses on horizontal competition (market power) and economic efficiency. The NPT framework ignores ‘vertical competition’, the competition for a higher percentage of the surplus value brought by innovation, and competition from complementary technologies that may challenge the lead position in the value chain of the incumbents (vertical innovation competition). We also need to consider the multiple dimensions and sources of ‘economic power’, horizontal and vertical, in the digital economy (e.g. intermediation power, algorithmic power, architectural power)¹²⁰⁹.
- Second, data and network effects require us to rethink competitive interactions beyond the traditional concept of relevant market. Some have put forward the view that the competition assessment should be done at the level of the platform¹²¹⁰. This may nevertheless challenge the important role of competitive markets as the main social institution to reward productivity. Competition law also needs to engage with the various forms of the competitive struggle to gain not only competitive advantage on product markets but also acquire architectural advantage, which is often more highly valued by financial markets, in view of its potential to sustain abnormal returns for a longer period of time. Competition analysis should engage with the ‘value capture strategies’ put in place by economic actors competing for strategic or architectural advantage in ecosystems¹²¹¹. Abandoning the sole focus on the relevant market also stems from the relatively more limited role of price competition in the digital economy (e.g. ‘free goods’ and multi-sided markets strategies). Hence, we need to develop new mapping tools that represent more accurately horizontal and vertical competitive interactions in the digital economy¹²¹².
- Third, the broader array of interactions, beyond market exchanges, between the different stakeholders, invites us to broaden our understanding of competition law, beyond the monocentric model focusing on price and output that has so far prevailed. In understanding the role of competition law in this new

1209 This derives from the central position of the agent in the network of various agents involved in this socio-technical system and capabilities to set the agenda for the rest of the network. I explore this further in I. Lianos et al, *Superior Bargaining Power in Competition Law: A Theoretical Analysis*, in I. Lianos, A. Ivanov & D. Davis, (eds.) *Global Food Value Chains and Competition Law: Towards Holistic Competition Law?* (forth. CUP, 2019) and in I. Lianos, V. Korah with P. Siciliani, *Competition Law: Analysis, Cases and Materials* (OUP, 2019), Chapter 8.

1212 See, *Global Food Value Chains and Competition Law – BRICS Draft Report* (January 1, 2018). Available at SSRN: <https://ssrn.com/abstract=3076160> or <http://dx.doi.org/10.2139/ssrn.3076160>; I. Lianos, *Digital Value Chains in Competition Law* (CLES Research Paper 1/2019), available at <https://www.ucl.ac.uk/cles/research-papers>.

environment, some prominent authors have suggested a 'broader reach for competition policy'¹²¹³ that would engage with the full social costs engendered by restriction of competition on different dimensions of well-being. Competition law will have to acquire a polycentric dimension in order to guarantee the effective protection of the societal values that may be affected by actors with economic power¹²¹⁴. However, we crucially lack the operational concepts, tools and metrics to develop this agenda further. Traditional equation-based modelling, although rigorous and insightful, may not cater for these very complex systems. We need to draw on the broader conceptual and methodological framework of 'complex economics'¹²¹⁵ which, we think, provides very interesting conceptual and practical insights in order to operationalise the complex systems that it becomes necessary to consider as competition law moves to tackle digital competition.

Chapter 5: The scope of competition law in the digital economy

Ioannis Lianos, Andrew McLean & Azza Raslan with Nicolo Zingales & Matthew J. Strader & the BRICS teams

5.1. Introduction

By defining and protecting property rights, ensuring the enforceability of contracts, allocating liability for harmful activities, imposing duties and burdens through regulation, law plays a central position in the organization of economic and social life, and significantly affects the process of development of capitalism, in view of the various path-dependences that different modes of social, institutional and economic development establish¹²¹⁶. The fact that the legal system did not specifically address the challenges of the digital economy by adapting its existing scope or expanding it accordingly may be explained, either by an active choice in favour of self-regulation through private governance regimes established by digital platforms (see Chapter 3) or by a choice imposed by innovation policy considerations and a new conception of the role of the State in the digital age.

We may distinguish between three main approaches linking the broader field of economic regulation by the State (including competition law) to innovation policy. First, a Schumpeterian approach that would accommodate the vision of a State that actively promotes product, process, organization and market innovation and that conceives its role as the enhancement of structural competitiveness of open economies to competition, what some have named ‘the Schumpeterian workfare state’¹²¹⁷. Even a regime of ‘permissionless innovation’ would require at least a (state) system of ensuring the adjudication and enforcement of property rights. Second, an approach inspired by the precautionary principle, with a pro-active intervention of the State in order to deter possibly harmful activities and to ensure that the principles and values of the Regulatory State will not be jeopardized. Third, an approach that would promote safe spaces for experimentation, for instance through the constitution of sandboxes, the State keeping away from implementing the law to pre-selected partners in a specific context (defined in terms of time, space, field of activity), while using this experience as a source of learn-

1216 As this is put forward by the literature on ‘varieties of capitalism’ and that on ‘legal origins’: See, P. Hall & D. Soskice, *Varieties of Capitalism – The Institutional Foundations of Comparative Advantage* (OUP, 2001); R. La Porta, F. Lopez-de-Silanes & A. Shleifer, *The Economic Consequences of Legal Origins*, (2008) 46(2) *Journal of Economic Literature* 285.

1217 B. Jessop, *Towards a Schumpeterian Workfare State? Preliminary Remarks on Post-Fordist Political Economy*, (1993) 40 *Studies in Political Economy* 7.

ing that would shape normative activity and implementation of the law in the future¹²¹⁸.

All these regulatory strategies of action, or inaction, have of course important implications for the balance achieved between the interests of the various stakeholders and the power of their claims for capturing a more significant part of the surplus value generated by innovation. What is also particularly interesting is that the pre-eminent role of digital platforms in digital capitalism and the subsequent implications this has on the economy, and the distribution of wealth may be explained by a conscious choice to expand the scope of application of a specific area of law, while receding from implementing another, or even adopting policies that would completely exclude the specific field from the legal forms of adjudication of disputes that rely on the monopoly of force from which benefits the State. These are questions that do not only relate to the (personal or material) scope of competition law, but that also concern its interaction with other policies and regulatory systems that have been put in place in each jurisdiction in order to achieve specific goals. It is important to distinguish here between these two separate although connected issues, which are often conflated in the literature by authors raising the risk of 'regulatory leveraging'¹²¹⁹: (i) the proper scope of the policy space of competition law, and once this is defined, (ii) the ability of the institutions enforcing competition law to venture into policy spaces other than that of competition law. Regulatory leveraging may be a concern with regard to the second issue, but it does not provide any guidance for the first one. Indeed, everything depends on what is considered to be the 'normal' scope of the activities of competition authorities and of the competition law policy domain in the specific jurisdiction, an issue that relates to the goals of the specific competition law.

This Chapter will first examine the challenges the digital economy sets to the scope of competition law. Second, we will delve into the way competition law interacts with other legal fields, and the intersection of the various remedial tools. Third, we will discuss the effectiveness of competition law remedies in the fast moving digital economy.

5.2. Adjusting the scope of competition law

The digital economy raises important challenges to the scope of competition law: personal, material and geographical.

5.2.1. The personal scope of competition law in the digital economy

It is important to take into account the various forms anti-competitive conduct may take in the digital economy and the risk that this may go undetected, or those responsible for the anti-competitive conduct not being found liable.

1218 On regulatory sandboxes, see FCA, Regulatory Sandbox (November 2015), available at <http://www.ifashops.com/wp-content/uploads/2015/11/regulatory-sandbox.pdf>

1219 W. E. Kovacic & D. A. Hyman, Regulatory Leveraging: problem or solution?, (2016) 23(5) *George Mason Law Review* 1163.

Hence, the first question one needs to ask with regard to the definition of the material scope of the competition law, is not ‘who’ is an undertaking but ‘what is economic activity’. Such analysis differs depending on the conduct examined and the facts of the specific case. It is possible that the same entity might be found to be an ‘undertaking’ for some activities but not qualified as such for other activities. The digital economy raises important questions as to the nature of the relations between labour and labour platforms and the scope and role of competition law intervention in labour markets in the digital age (see Sections 5.2.1.1., 5.2.1.2., 5.2.1.3.).

It is also crucial to examine the various forms of anticompetitive conduct in the context of blockchain, before answering the question, each time in view of the specific facts, as to whether the activity in question could be qualified as ‘economic’ and, thus, the entity exercising it, an ‘undertaking’ (Section 5.2.1.4.).

5.2.1.1. Labour and Competition Law in the Digital Economy

Another risk is that in view of the dominant role of digital platforms in the world economy, and the ‘winner-take-most’ competition game, where ‘superstar firms’ command growing market shares and become highly profitable, the labour’s share is in significant decline¹²²⁰. The forms of labour in the digital economy have also dramatically changed. However, despite the weak position of labour vis-à-vis the digital platforms, there are fewer possibilities of labour to organise and collectively bargain with digital platforms, as this may fall under the scope of competition law. As we have examined in Chapter 4, promoting the collective bargaining of the different actors (suppliers, labour, users) in the value chain vis-à-vis digital platforms holding ‘bottleneck’ or positional power may offer some remedy to the negative effects of the exercise of such power by the digital platform. The idea is that a two-way bottlenecks could be better (from an efficiency perspective) than one-way bottleneck. We will explore how the institution of collective bargaining may take care of some of the social costs imposed by dominant digital platforms.

5.2.1.1.1. Defining the problem

Competition law usually applies to entities exercising an economic activity in an independent (non-subordinate) way. This may raise difficulties in view of the changing nature of labour relationships in today’s ‘gig’ or ‘collaborative’ economy and the collapse of the traditional binary divide between employment and self-employment. The classic example is how competition law would address the relation between Uber and Uber drivers.

The most important implication of the shift from an ‘old-economy business model’ (OEBM) to ‘new-economy business model’ (NEBM) was in the areas of employment, la-

1220 D. Autor, D. Dorn, L. Lawrence, F. Katz, C. Patterson & J. Van Reenen, ‘Concentrating on the Fall of the Labor Share’, (2017) 107(5) American Economic Review 180.

bour organization, and labour benefits¹²²¹. The dismantling of life-long and secure employment built on mutual loyalty and commitment of employers and employees, which was the hallmark of industrial capitalism, in favor of short-term and insecure employment of a mobile workforce that is always on lookout for new opportunities is a well-documented and well-understood story of labour in the latter part of the 20th Century.¹²²² In broad outline, this was a story of precariousness, the decoupling of benefits (health, retirement, etc.) from employment, and the turning of individuals and households into units of risk management and entrepreneurship.¹²²³ In light of this story, the rise of platforms and the emergence of so-called gig economy in the first part of the 21st century can be considered ‘natural’ and ‘logical’ extensions of the developments of the earlier decades.

Box 1 The Gig Economy in BRICS Countries

Some BRICS NCAs have dealt with issues arising from the gig economy and the sharing economy.

BR In the recent years, CADE dealt with some cases involving companies in the “gig economy”. In 2015, CADE analyzed a merger between Tiger Global Management LLC, an investment fund management company, and GetNinjas, a gig economy platform that intermediates local services, like house cleaning, painting, home renovation, classes and others. It was an indirect acquisition by TGM of a stake in GetNinjas, through the acquisition of shares of GetNinjas Cayman. The transaction was approved without restrictions. In 2017, CADE analyzed a merger involving the online food delivery market, between Rocket Internet SE (Delivery Hero) and Naspers Ventures B.V. (iFood and Spoonrocket). The transaction was approved without restrictions.

RU The Law on Protection of Competition does not include any exemption for any kind of self-employed people (including those of gig economy). In 2016 the FAS Russia approved with conditions the merger of taxi platforms Yandex and Uber, which are the specific examples of the gig economy. While considering the merger the FAS Russia took into account the specific features of merging platforms.

CN Cases related to the gig economy involve mainly the express delivery industry and the online car-hailing industry. In 2017, SAMR unconditionally approved Jiangsu Suning Logistics Co., Ltd. to acquire the equity of Tiantian Express Co., Ltd., which concerned the same city express service market, the provincial express service market and the inter-provincial express service market. From 2018 to 2019, SAMR unconditionally approved cases related to online car-hailing, including the joint venture case between Toyota Motor Corporation and Softbank Co., Ltd., the joint venture case of Geely Technology Group Co., Ltd. and Daimler AG, and the acquisition of Beijing Bao by Shenzhou UCAR Co., Ltd., and the equity case of Wo Automobile Co., Ltd.

Looking to the category of ‘work’ (see Figure 5.1), we can identify two separate poles and then a number of situations that lie in the middle.

Figure 5.1: Dissecting the Category of ‘Work’ (compensated)

Source: I. Lianos, N. Countouris & V. De Stefano, *Re-thinking the competition law/labour law interaction: Promoting a fairer labour market*, (2019) *European Labour Law Journal*,

We are inspired here by the classic distinction between ‘hierarchy’, conceived as a centralized pole of economic organization of production regulated by the employment contract and characterized by the hierarchical position of management¹²²⁴, and the ‘market’, considered as a decentralised institution that relies, in order to function, on price signals emitted by consumers/users of labour (as the archetypical market in our case will be labour markets), to which labourers strive to respond. The key concept characterizing hierarchy is the full control of labour to the extent that this is integrated in an existing hierarchical structure. Of course, labour here is compensated though the payment of a wage by the employer. We do not distinguish for the purposes of this study between employers that are corporations and employers that are physical persons. Waged work is not the only category of supervised labour that may be integrated into the hierarchy. It is also possible to think of certain dependent professionals, for instance lawyers acting for a significant part of their time as in-house counsel for corporations, as also integrated into the boundaries of the firm.

While waged work constitutes one pole of ‘work’, the other one is constituted by labour expended in order to manage capital, own or capital borrowed in financial markets. The second pole of ‘work’ relies on the use of capital, the most extreme scenario being that

¹²²⁴ Depending of course on the theory of the firm one may adopt.

labour becomes marginal or ancillary to the use of capital. This may include different forms of entrepreneurship (e.g. a restaurant owner that is at the same time the restaurant chef). In the middle, lie a certain number of alternative working arrangements that associate a worker to a specific task, but without integrating the worker in the hierarchy, as the worker remains in principle free to also provide work for other 'employers', although this formal freedom may be regulated, for instance, by non-competition clauses in the contractual relation. This category includes part-time workers, or gig and app work. This type of work has considerably increased in importance the last three decades, as a result of the transition process from OEPM to NEPM.

A study conducted in the US, for instance, surveyed temporary help agency workers, on-call workers, contract workers, independent contractors, and freelancers, and found that their share in the entire worker-force rose from 10.7% in 2005 to 15.8% in 2015 — a 50% increase in 10 years.¹²²⁵ By comparison, there was hardly any change in this regard between 1995 and 2005. More telling, 95% of the net employment growth in the US economy (2005-2015) occurred in alternative work arrangements, while for standard employment arrangements the growth amounted to only 0.4%. There are predictions that the majority of U.S. workers will be freelancing by 2027, thus leading to a very different structure of the labour market¹²²⁶. Although 44% of freelancers gained more than US\$50000 gross income per year in 2018¹²²⁷, more than half of them work in more than two jobs, with five percent reporting having simultaneously four jobs or projects in order to be able to gain this income¹²²⁸.

The situation is also rapidly evolving in Europe. There were more than 1 million freelancers in the UK in 2017, the most populous occupation for being in the artistic, literary and media sectors¹²²⁹. These reported average earnings of approximately £29000, the medium annual earnings for full-time workers being during the same period £28760.

Of particular interest is the development of alternative work arrangements which are facilitated by digital platforms, which create new digital marketplaces to supply labour for temporary use ('labour value platforms')¹²³⁰. Schmidt provides a comprehensive taxonomy of these work arrangements, identifying two major categories each with three sub-categories, (i) Web-based Cloud work (which comprises freelance marketplaces, microtasking crowd work, and contest-based creative crowd work), and (ii) location based 'Gig' work (accommodation, transportation and delivery services, and household and

personal services)¹²³¹. This work may sometimes be categorised under the wide umbrella of Non-Standard and contingent work (self-employed own account workers not hiring other individuals, temporary or fixed term contracts, and part-time work), although the way the work is organized, and the lack of alternatives in view of the dominance of these platforms, may be compared to the relation between employer and employee in traditional and long-term forms of employment¹²³².

An increasing number of people provide services through online platforms such as Uber, Grubhub, Upwok, Handy, Deliveroo or TaskRabbit. The rise of these kinds of 'gig work' is becoming a global trend. It has been reported that of the 150.000 new jobs created in Denmark 2012-2017, 44% were part-time jobs with 20 working hours per week or less, despite its strong unions and social contract between employers and employees.¹²³³ Other studies report similar trends. For instance, a study by JPMorgan-Chase (Farrell et al. 2016) found that 0.9% of adults in the USA participate in the online platform economy — 0.5% on labour platforms of the gig-economy (e.g. Uber, Taskrabbit) and 0.4% on capital platforms, leasing or selling their assets (e.g. Airbnb, eBay). Importantly, these numbers are the result of remarkable growth, which reached the 400% mark in late 2013 and most of 2014 before it slowed down to 102% in mid-2016. However, such growth is counteracted by high turnover rates; around one in six participants is new at any given month, while ca. 50% of participants exit within 12 months.

The 'gig' economy is usually understood to include chiefly two forms of work¹²³⁴: 'crowd-work' and 'work on-demand via apps'. The first term is usually referred to working activities that imply completing a series of tasks through online platforms. Typically, these platforms put in contact an indefinite number of organisations and individuals through the internet, potentially connecting clients and workers on a global basis. IT platforms are used to source work 'from an anonymous group of "bidders", who are referred to as the crowd, the provider and the worker frequently not having direct contact¹²³⁵. "Work on-demand via apps", instead, is a form of work in which the execution of traditional working activities such as transport, cleaning and running errands, but also forms of clerical work, is channelled through apps managed by firms that also intervene in setting minimum quality standards of service and in the selection and management of the

workforce¹²³⁶. For instance, transport platform Uber uses technology to match customers with persons delivering work in the real world, such as offering a ride (cab services), delivering items (courier services), caring for children, the elderly or pets, gardening, or other craft services”¹²³⁷. The second relies on the IT platform (through an app) to source work ‘from an anonymous group of “bidders”, who are referred to as the crowd, hence the name crowd sourcing’, where frequently the provider and the worker will not have direct contact as the process is organised through the IT platform¹²³⁸. These archetypes ‘represent points on continuum’¹²³⁹.

App-work consists in a digital platform matching a user/consumer with a pre-selected, by the platform, professional ‘user’ of the platform, who is already exercising this type of activity, and although in theory independent and self-employed, in reality relies on the platform technology, often through an app, to reach consumers/users at the other side of the platform. This pre-selection process and the fact that inclusion in the platform to be ‘matched’ with a user from the other side requires some form of governance of the platform with specific rules to which the app workers may abide to. Hence, this type of work may appear quite close to a traditional employment relationship, although there is no payment of wages in this occasion. Notwithstanding the non-integration of these workers in the hierarchy, for instance through the existence of a formal employment contract, the fact of the matter is that they also depend for their livelihood on their technological inclusion in the digital platform ecosystem. Often their relation with the platform takes the form of a commercial agency agreement, the genuine agency relations supposing that the agent acts as the long hand (*longus manus*) of the principal. However, courts have been quick to re-qualify these arrangements as functionally equivalent to employment, in view of certain characteristics accentuating this relation of dependence¹²⁴⁰.

Crowd-work may also lead to situations of dependence, if competition is limited because of the dominance of a platform on a specific (labour) market, or because of exclusion

1240 See, for instance, the approach of the UK Employment Tribunal (UKEAT) regarding the employment status of Uber drivers: *Uber B.V. and Others v Mr Y Aslam and Others*: UKEAT/0056/17/DA. The UKEAT rejected the label of agency used in the written contract between Uber and the drivers and qualified them as employees, although the drivers incurred commercial risks as they were responsible for all costs incidental to owning and running the vehicle, and were also able to work for or through other organisations, including direct competitors with Uber operating through digital platforms. The UKEAT arrived to this conclusion by adopting a purposive interpretation, taking into account the relative bargaining power of the parties, the integration of Uber drivers into Uber’s business, in particular as, among other things, they were prevented from building up a business relationship with the end user of the service, they were in practice obliged to accept all trip requests if they wanted to keep their account status, and Uber held a significant market share in London, which left them no other equally effective competitive alternative.

ary strategies adopted by the platform. However, to the extent that the crowd worker is able to work for other platforms and collect an equal or significant part of his revenue from them, dependence becomes less of an issue. Dependence will of course increase the more the crowd-worker depends on work for a specific platform, in which case his situation may be considered as functional equivalent to a full-dependent worker.

The introduction of computing into work environments has profound implications on the nature of the working relation and requires a more functional perspective in envisioning the concept of 'work'. This should integrate the change from EOBM to NEBM, as well as the reality of the technological dependence of labourers to 'matching' platforms. Those involved in alternative work arrangements often find themselves in the role of entrepreneurs, drawing on their own personal assets, with all the attendant risks and rewards to this kind of economic activity¹²⁴¹. Gig workers find themselves in the grip of the so-called platform economy, controlled by machines and managed by algorithms, into the working of which they do not have any access or insight, and with no recourse to legal labour protections.¹²⁴² These changes also affects labour in different ways: low-skilled workers are facing stagnant or declining wages with an increasing prospect of intensified work through computer-coordinated mechanisms, while high-skilled professionals might be cognitively augmented in carrying out their work, and mid-level workers face the risk of job loss through technologies of automation. The net effect of these developments on waged labour is the 'hollowing out' of middle class, as observed in various societies¹²⁴³.

Digitalization has also made possible the emergence of other value-generating activities that may not fit well within the strict boundaries of the concept of 'labour' as this was conceived by the traditional 'labour theory of value' of classical economists during the era of industrial capitalism. These varieties of human activity not only contribute different forms of value that go beyond traditional labour theory of value, they also involve different social roles and different forms of relation to modern technology. We will refer to the concept of 'use' as a separate concept from that of labour. Indeed, the human activity of 'use' cannot only be characterized as productive, to the extent that the production of value involves some act of consumption for own purposes, as opposed to the consumption of an input in order to produce an output that is considered as a

production activity. The fact that use may generate value questions the idea that value may only be generated by a social relation of production. Similarly, 'use' cannot be confined to an act of consumption, and the two concepts should therefore not be conflated, precisely because of the fact that it generates value.

One may distinguish between different forms of 'use' (see Figure 5.2). The first consists in activities that were previously undertaken by waged workers, labourers with alternative working arrangements, or other types of value-creating labour but which modern computing technology and digitalization has made it possible to heteromate to the users of computing technologies. We will broadly refer to this as 'heteromated labour'.¹²⁴⁴ A classic example is that of the self-serving customer of an airline proceeding to checking in for his flight online, instead of completing this at the airport assisted by an airline representative. This auto-check in process constitutes a moment of heteromation. The process cannot be compared to automation, as human intervention is still required. However, this human activity is that of the customer who auto-checks in. The customer offering this 'labour' remains uncompensated, the value generated being captured by the airline company.

Figure 5.2: Varieties of use

Source: I. Lianos, N. Countouris & V. De Stefano, *Re-thinking the competition law/labour law interaction: Promoting a fairer labour market*, (2019) *European Labour Law Journal*

The situation becomes more complex if the activity is new and there is no possibility to compare with an activity previously exercised by labourers. One may envisage the example of a 'You Tube' user, who has the passion of making videos and then to upload and 'share' them on 'You Tube' for everyone to watch. This activity remains in general uncompensated, although some 'You Tubers' have turned their passion to a career, for instance by using the 'You Tube' Partner Program that enables those posting videos to be paid through views and through advertisements served on their page if they have

¹²⁴⁴ H. Ekbja & B. Nardi, *Heteromation, and Other Stories of Computing and Capitalism* (MIT Press, 2017).

reached a certain number of ‘watch hours’ and number of subscribers that makes them eligible for the programme. The money is made through advertisements, paid either on the basis of how many viewers click on the ads surrounding the video (cost per view) or the number of viewers of the ad for more than 30 seconds (cost per thousands views). If this activity of making videos is compensated, it may constitute entrepreneurship, while if it is uncompensated it can be characterized as heteromated ‘labour’ or ‘heteromated use’. These activities are commoditised, in the sense that, before being heteromated, they were exchanged in a market for a price, in case these were considered as an input bought in the market of services, or compensated by a wage in the marker for labour, had these been performed by a worker hired for this purpose.

Another example is that of a ‘Facebook’ user. In addition to being a social network, Facebook may be considered as the most popular media company in the world, although it does not create any content itself. It simply constitutes a platform enabling Facebook users to create content either by posting original content, in the form of blog posts, photos videos, opinion pieces, or by sharing hyperlinks to media content available in other platforms. The activity of the Facebook user creates value, to the extent that it attracts other users in the platform. However, this activity remains uncompensated. The Facebook user certainly benefits from the content created on the platform, and the fact that interesting content is available constitutes certainly one of the reasons of the use of Facebook at the first place. However, to the extent that the content created by the Facebook user may be visible by all the Facebook network users, and not just by those with whom the user initially selected to share it (e.g. his Facebook friends), one may infer that some value generated from the Facebook’s use is only captured by the platform (not the user). This may constitute an example of ‘heteromated use’, if it cannot qualify as ‘heteromated labour’, to the extent that generating content in media may be considered as a form of labour.

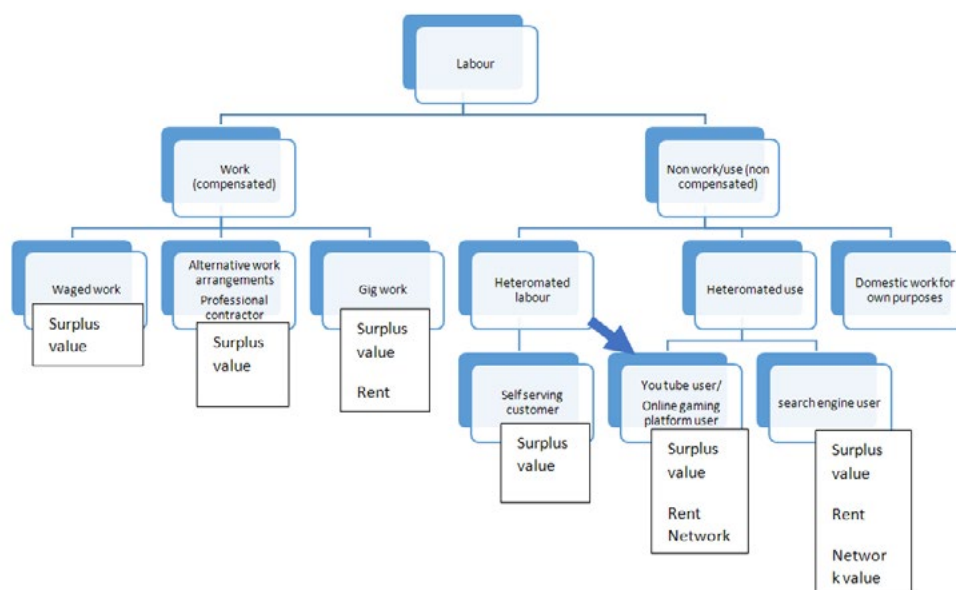

Another example may be that of a gamer in the context of player versus player (PvP) on-line gaming platforms, where players compete against each other, rather than against computer-controlled opponents. The simultaneous use of the platform by different players enables the platform to offer multiple opportunities to the various players to play games and try their skills. It thus directly contributes to the gaming service provided by the platform, as the PvP platform would have no use had there not be a sufficient number of players to play against each other. To the extent that the gaming platform charges for its services, part of this value is captured by the platform, the level of capture depending on the market power of the specific gaming platform (monopoly rents). However, the platform is also able to collect data on how players are using the games in real time, data harvested not only with the purpose to improve their gaming experience, but also in order to be monetized in various ways in data markets, thus constituting another example of ‘heteromated use’. This surplus value is entirely captured by the gaming platform.

Finally, one may refer to the situation of a user of a search engine, such as Google Search. The user is not charged a price for the use of the search engine, but Google

harvests the data of the user, not only with the purpose to improve the user experience but to sell predictions made on the basis of this raw data to advertisers at the other side of the platform. These predictions rely on the aggregation of different sources of data, some harvested by Google on the specific user, groups of other users being classified in the same personality type¹²⁴⁵, or other publicly available data harvested by other platforms to which Google has access or buys access to. Certainly, some of the data harvested by the user is re-employed in order to improve the accuracy of the search engine to the specific user (through more personalization of search) and thus better overall search quality. The user also benefits from the searches done by other users, as the training of search algorithms with more data improves the quality of search, in particular for tail queries (learning effects resulting from the increase of the network of users). However, a significant part of this surplus generated by these network effects is captured by the platform, to the extent that adding more users increases the attractiveness of the Google Search platform for advertisers at the other side of the market (indirect network effects). One may also add the value generated by the ability of the search engine to predict the preferences of users in future transactions by drawing relatively accurate maps of the user's preferences, or by the ability of the platform to manipulate the user's choice. This potential for future abnormal profits is highly priced by financial markets, bringing the valuation of some of these digital platforms at astronomical levels. One may consider that this also constitutes an example of 'heteromated use', to the extent that the simple use of the search engine generates surplus value as well as network value. In the presence of significant network effects and because of the emergence of digital monopolies, the user is not able to capture an equal part of the surplus value or the network surplus to the level of his contribution. First, the user has no information on the real value (and cost) of his data, as these are sold in the advertising side of the platform and these exchanges and their conditions are not visible to his side of the platform, his relation with the platform therefore being characterized by an important informational asymmetry. Second, even if the user had such information, one could not have expected the individual user to be in a position to bargain with the platform a 'fair' share of the surplus generated, in view of the strong bargaining power of the latter resulting from its monopolistic position and the 'take it or leave it' nature of the exchange. Indeed, the search engine user has to comply with the terms and conditions of the search engine or platform for its 'free' use.

Figure 5.3. attempts to present a simplistic scheme of the sources of surplus value for each of the processes we examined.

As Ekbia and Nardi demonstrate, depending on the specific technology and context of use, this type of ‘heteromated labour’ or ‘heteromated use’ can take various forms: cognitive, creative, communicative, emotional, and organizing¹²⁴⁶. Value is produced in different forms through heteromated use and labour in daily transactions of people with various technologies — from social media and gaming to search engines and so-called self-service systems in different localities (shopping, banks, airports, etc.). The mechanisms of value extraction vary in each specific case — advertising on social media and search platforms, creative labour in gaming, and data capture and analysis in many of them — but the common denominator among these is the social process of exclusion through inclusion and engagement, which turns these into subtle and hidden mechanisms that need to be unveiled through closer examination.

A different approach than the labour theory of value followed in this Section would have focused on the rise of labour market power. Labour market power has been defined as ‘the ability of employers to set wages below workers’ marginal revenue product’, which denotes the existence of labour exploitation, a concept that has nothing to do with the concept of exploitation employed by the labour theory of value inspiring Marxist approaches, as it only focuses on the exploitation of labour by virtue of the imperfection of the (labour) market¹²⁴⁷. A labour market has been defined as ‘a group of jobs, between which workers can switch with relative ease (for example, computer programmers, law

¹²⁴⁶ H. Ekbia & B. Nardi, *Heteromation, and Other Stories of Computing and Capitalism* (MIT Press, 2017).

¹²⁴⁷ See, J. Robinson, *The Economics of Imperfect Competition* (MacMillan, 1933), 283, noting that ‘a group of workers are being exploited when their wage is less than the marginal physical product that they are producing, valued at the price at which it is being sold’.

yers, or unskilled workers) located within a geographic area usually defined by the commuting distance of workers'.¹²⁴⁸ The concept assumes that there exists a 'spot market' for labour hours, firms employing a number of workers for a specific amount of hours. Under the profit maximization principle, a firm would employ a number of workers whose net marginal product equals the marginal cost of labour, in terms of wages paid. One may conceive the employment relation as a joint venture between owners of capital and workers to the extent that firms combine labor (L) and capital (K) to produce output (Q). The marginal product of a typical worker varies over time. Joan Robinson employed for her definition of exploitation the 'marginal physical productivity of labour', which she defined as 'the increment of output caused by employing an additional unit of labour with a fixed expenditure on other factors'¹²⁴⁹. The employment relationship results in a gap between the workers' marginal product at the firm and their alternative wage offers (in real terms). According to Robinson, exploitation may occur due to the workers' weaker bargaining power than the employers', the 'fundamental cause' of exploitation being 'the lack of perfect elasticity in the supply of labour or in the demand for commodities'¹²⁵⁰. Exploitation may be monopolistic, if this results from imperfections in the commodities market (even if the labour market is competitive), or monopsonistic, if this is due to imperfect elasticity of the supply of labour (even if the product market is perfectly competitive)¹²⁵¹. In situations of monopsonistic exploitation, the wage would equal the supply price of the employee, which would be inferior, because of imperfect competition, to the value of the marginal physical product of labour. Although a minimum wage would remove this kind of exploitation, it would also have as an effect to increase production costs, and therefore lead to a number of negative effects. First, it may increase prices for consumers, if these high costs would be passed on to the consumers in the commodity market, hence workers may lose as consumers more than what can be offset by their gain as wage earners. Second, it may lead to labour factor substitution with a decrease in the level of employment. An important source of labour market power is monopsony and oligopsony resulting from the product and labour markets concentration that has been documented in various industries in recent years¹²⁵². This provides a higher bargaining power to capital and enables firms to 'markdown' wages below the marginal revenue product, redistributing from workers to employers, which has both distributive justice implications, as well as produces deadweight loss (to the extent that it may lead to unemployment)¹²⁵³.

5.2.1.1.2. Re-inventing new legal categories?

The development of platform work raises interesting questions, as to the criteria that would enable courts and public authorities to distinguish between workers and self-employed and have raised questions as to the pre-eminence of the employment test as to whether the alleged employer has the right to control the manner and means of accomplishing the result desired in both labour and competition law.

It certainly raises interesting questions as to the respective scope of labour law and competition law and their respective roles in engaging with, and regulating, these new emerging labour market dynamics. Traditionally, competition law focused on safeguarding competition on product markets, labour markets being, with a few exceptions, beyond its remit. This is partly due to the fact that competition law is traditionally perceived as regulating transactions taking place in the context of the market form of organisation, leaving hierarchies, that is relations taking place inside the firm, outside of its scope¹²⁵⁴. In contrast, labour law has traditionally focused on the regulation of the standard employment relationship embedded in the typical contract of subordinate employment, although in recent decades its focus has partly expanded to include some emerging forms of so-called atypical work relations, such as part-time, fixed-term, and temporary work.¹²⁵⁵ In the view of the present authors, this traditional allocation of tasks between employment law and competition law may not be fit for purpose in the era of the New Economy Business Model and the multiplication of alternative forms of labour.

Labour law typically draws a distinction between subordinate ‘employees’ and the autonomous ‘self-employed’. Some Member States (E.g. Spain, the UK, Italy, Germany, Austria...) contemplate intermediate categories of semi-dependent workers, that are usually understood as sub-categories of self-employment.¹²⁵⁶ Other Member States (e.g. France, Belgium, Sweden) do not contemplate intermediate categories, but their notions of ‘worker’ are very broad and include several personal work providers that in other systems would be seen as ‘self-employed’ persons. The concept of self-employment operates as a residual category: if a person does not meet the often very detailed criteria and indicators used to identify who is an ‘employee’ or ‘worker’, labour law will assume, almost by default, that that person is self-employed. Because of this approach, the concept of self-employment encompasses a very broad and heterogeneous range of service providers. It can include both self-employed persons that exclusively sell their

Fudge, ‘A Canadian perspective on the scope of employment standards, labor rights, and social protection: The good, the bad, and the ugly’ (2010) *Comparative Labour Law and Policy Journal*, Vol. 31, No. 2, pp. 253–266. See also the various chapters in the present special issue.

personal labour (often to a single client or to a limited number of clients or customers), but also self-employed persons that offer highly capitalised services, including by recruiting staff in order to offer such services.¹²⁵⁷

Of particular interest is the recent judgment of the Supreme Court of California in the *Dynamex* litigation¹²⁵⁸. Emphasizing the statutory purpose as the touchstone for deciding whether a particular category of workers should be considered employees rather than independent contractors, the California Supreme Court distinguished between three standards in determining the boundary between ‘workers’ and ‘self-employed’ for the purposes of the ‘wage orders’ under the state law in California which provide minimum wage, maximum hour, and working condition requirements for specific industries.

First, there is the common law standard of the hirer’s right to control the details of the work, which as we described above also inspires the approach followed in EU law, which is often supplemented by a number of secondary factors that assist the decision-maker in the implementation of the test¹²⁵⁹. Second, the US courts have developed the ‘the “economic reality” (or “economic realities”) standard’, which treats as employees ‘those workers who, as a matter of economic reality, are *economically dependent* upon the hiring business, rather than realistically being in business for themselves’¹²⁶⁰. Again, the courts make a multi-factor determination focusing, *inter alia*, on ‘the workers’ opportunity for profit or loss and their investment in the business’, ‘the degree of skill and independent initiative required to perform the work’, ‘the permanence or duration of the working relationship’, and ‘the extent to which the work is an integral part of the employer’s business’¹²⁶¹. As the second test requires a significant effort of analysis, some US courts adopted the simpler and clearer ‘ABC standard’¹²⁶². This standard places the burden on the hirer to establish that the worker is an independent contractor by assuming that the worker is an employee, unless the hiring entity cumulatively satisfies the following three factors: (A) ‘that the worker is free from control and direction over performance of the work, both under the contract and in fact’; (B) ‘that the work provided is outside the usual course of the business for which the work is performed’; and (C) ‘that the worker is customarily engaged in an independently established trade, occupation or business’¹²⁶³. According to the California Supreme Court in *Dynamex*, the ABC test provides a less wide-ranging and flexible test than the ‘economic realities’ standard. The Court suggests to start by examining factors B and C first, before moving to

1257 Cf. N. Countouris and V. De Stefano, *New Trade Union Strategies for New Forms of Employment* (ETUC, 2019).

1258 *Dynamex Operations West v. Superior Court of Los Angeles County*, 4 Cal.5th 903 (2018).

1259 These are, in addition to the control of the details of work the following five, thus constituting a ‘six-factor test’: (1) the alleged employee’s opportunity for profit or loss depending on his managerial skill; (2) the alleged employee’s investment in equipment or materials required for his task, or his employment of helpers; (3) whether the service rendered requires a special skill; (4) the degree of permanence of the working relationship; and (5) whether the service rendered is an integral part of the alleged employer’s business’. The Court cites *S. G. Borello & Sons, Inc. v. Department of Industrial Relations* (1989) 48 Cal.3d 341, 354-355.

1260 *Dynamex Operations West v. Superior Court of Los Angeles County*, 4 Cal.5th 903 (2018), fn 20 (emphasis added).

1261 *Ibid.*

1262 *Ibid.*

1263 *Ibid.*

the more evidentially demanding factor A, if need be. For instance, if a worker has not independently decided to engage in an independently established business but instead was simply designated an independent contractor by the unilateral action of the hiring entity, then there is a high risk of misclassification and the factor C may not be satisfied. Furthermore, concerning factor B, the courts should examine if the role in question is comparable to that of employees in the specific course of business of the hiring entity. Factor A is similar to the common law standard previously examined. The judgment of the California Supreme Court has important implications as to the qualification of the activity of platform workers, and therefore the personal scope of labour law protection. It may also provide inspiration as to the possible use of similar factors under EU labour law. By referring to the existence of economic dependence as a relevant factor for the qualification of the distinction between ‘employees’ and ‘self-employed’, it hints to the possibility that a common criteria, based on economic realities, may apply for both labour law and competition law.

In most competition law systems, including the EU law one, the concept of ‘undertaking’ is widely interpreted as ‘an entity engaged in economic activity’¹²⁶⁴. It includes individual persons offering goods or services on a market where they bear financial risk attached to performance of those services¹²⁶⁵. However, an employee cannot be an undertaking as it does not exercise an autonomous economic activity, in the sense of offering goods or services on a market and bearing the financial risk attached to the performance of such activity. So when workers combine with each other and conclude collective agreements with employers to fix a rate, or a price, for the sale of their labour, competition law systems typically see these practices as something quite distinct from the price fixing practices that undertakings may be engaging in.¹²⁶⁶ For instance, since *Becu*¹²⁶⁷, the possible application of Article 101 TFEU to collective agreements concluded between trade unions and associations of employers has led to the development of a fully-fledged exception to the application of EU competition law, for reasons of social policy.

The situation of employees is dealt differently in the EU than in the US. In US law all ‘persons’ are subject to the Sherman Act, unless they benefit from an exemption. Labour benefits from a statutory and a non-statutory exemption. The statutory labour exemption¹²⁶⁸ enables workers to organize to eliminate competition among themselves, and to pursue their legitimate labour interests, so long as they act in their self-interest and do not combine with a non-labour group. Yet, the statutory labour exemption did not immunize the collective bargaining process or collective bargaining agreements themselves from potential antitrust liability, but covered only labour’s organizations unilateral actions. The US courts thus developed the non-statutory basis of the labour exemption in order to remove from antitrust scrutiny restraints in trade that are the product

of a collective bargaining agreement between labour and management¹²⁶⁹. These more typically apply to agreements between employees or their unions and employers when the agreements are intimately related to a mandatory subject of bargaining, and do not have 'a potential for restraining competition in the business market in ways that would not follow naturally from elimination of competition over wages and working conditions'¹²⁷⁰. According to the US Supreme Court)¹²⁷¹, '[t]he non statutory exemption has its source in the strong labor policy favoring the association of employees to eliminate competition over wages and working conditions. Union success in organizing workers and standardizing wages ultimately will affect price competition among employers, but the goals of federal labour law never could be achieved if this effect on business competition were held a violation of the antitrust laws. The Court therefore has acknowledged that labour policy requires tolerance for the lessening of business competition based on differences in wages and working conditions'. Courts have even extended this immunity beyond the expiration of a collective bargaining agreement¹²⁷². The non-statutory labour exemption has been frequently applied in the field of professional sports, for instance exempting a labour agreement between the US National Football League (NFL) or the National Basketball Association (NBA) and a national union of student-athletes¹²⁷³.

However, exercising a liberal professions has usually being found to constitute an economic activity falling under the scope of competition law if there is no relation of employment.¹²⁷⁴ In principle, it is not possible to exclude from the scope of Article 101(1) TFEU collective agreements concluded between the members of liberal professions with regard to the fixing of minimum rates or other agreements restricting competition between them, to the extent that self-employed are considered to be undertakings¹²⁷⁵. In its most recent case law, the CJEU has taken a more circum-spect view of the implications for the scope of EU competition law of the distinction between workers and self-employed persons, suggesting that the effective scope of EU competition law with regard to the self-regulation by the social partners of labour relations may be less based on categorical distinctions between workers and self-employed than on their conceptualization as a *continuum* going from situations of complete dependence (in which case the relation will be considered as akin to employ-

ment) to a situation of complete independence (in which case the entity in question will be considered as an independent undertaking).

Cases such as *FNV Kunsten*¹²⁷⁶ raised the crucial question of the scope of competition law in view of the emergence of forms of work relationship, such as platform-based work, that put the traditional binary divide between employment and self-employment under strain.¹²⁷⁷ It also raised important questions as to the optimal boundaries between competition law and labour law, and the possible extension of the workers' protection to the 'new jobs', a politically sensitive issue.¹²⁷⁸ In 2006, a collective labour agreement laying down minimum fees for 'employed' and 'self-employed' musicians substituting for members of an orchestra was concluded in the Netherlands. However, it was terminated shortly afterwards, as the Dutch Competition Authority was of the opinion that it was anti-competitive under Article 101 (1) TFEU. The national proceedings initiated by the trade union led to a request for a preliminary ruling to the Court of Justice of the European Union, which surprisingly asserted its jurisdiction despite the lack of any cross-border element. The Court put in place an exception to the application of competition law rules for 'false self-employed'. The CJEU expressly suggested that 'if the service providers, in the name and on behalf of whom the trade union negotiated, are in fact "false self-employed", that is to say, service providers in a situation comparable to that of employees', then Article 101(1) TFEU will not apply to these agreements¹²⁷⁹. The CJEU in *FNV* relied on the following two criteria for defining 'false self-employment':

- *Dependence*: 'the person does not determine independently his or her conduct on the market'¹²⁸⁰, or 'the person is economically dependent on a main customer'¹²⁸¹, with the understanding that the person could be dependent on a main customer even if she derives an income from other customers as long as that additional income is marginal or ancillary. The Court accepts that 'a service provider can lose his status of an independent trader, and hence of an undertaking, if he does not determine independently his own conduct on the market, but is entirely dependent on his principal, because he does not bear any of the financial or commercial risks arising out of the latter's activity and operates as an auxiliary within the principal's undertaking'¹²⁸².

- *Relationship for specified period of time*: The service should be performed for and 'at direction' of principal, particularly in respect of time, place, and content of work.

We submit that competition authorities should issue guidance documents providing a specific clarification of the term 'worker' for the purposes of the application of competition law as amounting to

'A worker is a person that for a certain period of time is engaged by another to perform mainly personal work or services in return for which he receives remuneration.

Such work or services may be performed under the direct control, indirect control, or decisive influence of the employer or involve a duty to cooperate with employer's direct or indirect instructions"¹²⁸³.

Alternatively, one may not only choose to promote the position of workers, because they are the weaker party in the exchange or because they suffer from a position of structural inequality, but also the broader interest of the public (consumers and entrepreneurs) for innovation. Innovation may be jeopardised if the platform is not able to gain some profits, and thus be appropriately rewarded for its investment. This difficult balancing act may arguably call for the establishment of a new 'hybrid category', situated between the concept of 'worker' and that of 'self-employed'. Those in the hybrid category would only benefit from some aspects of labour protection, or at least be able to collectively bargain with the digital platforms in the presence of asymmetric bargaining power in order to guarantee the right to 'appropriate and proportionate remuneration', as the minimum required in order to reward productivity and maintain incentives¹²⁸⁴. The introduction of a hybrid category would enable firms to retain control of some actions while their workers would control others.

One may consider that the expansion of the category of workers, as suggested in the previous paragraphs, can impose an important cost burden on platforms, leading them to make inefficient choices regarding the degree of control and the revenue shares given to their workers¹²⁸⁵. Assuming a single costly revenue-enhancing action, the question is who, the platform or the worker, should retain control of that activity. This has in turn implications on who should benefit from the larger share of variable revenue in this case¹²⁸⁶. When workers control the costly action, the platform must give them a larger share of variable revenues in order to incentivize them to choose high levels of the action. Hagiu and Wright observe that 'real-world platforms typically let workers keep a large share of the revenues generated, but at the same time provide no fixed payments to the workers by way of salaries or other fixed benefits'¹²⁸⁷. The same authors note that

¹²⁸³ See the proposals in I. Lianos, N. Countouris & V. De Stefano, Re-thinking the competition law/labour law interaction: promoting a fairer labour market, (forth. 2019) European Labour Law Journal.

¹²⁸⁴

¹²⁸⁵

¹²⁸⁶

¹²⁸⁷

'(i)n contrast, traditional firms that tend to take control over revenue-enhancing costly actions prefer to attract workers mostly through fixed salaries and benefits, since that leaves the firm with a greater share of variable revenue, thereby minimizing the distortions in its own choices of these actions'¹²⁸⁸. By emphasizing the transfer of control rights between the platform and the workers, this research allows for situations of two costly actions, where the efficient allocation of control rights would require the platform to control one and the worker to control the other. It also illustrates that the allocation of control rights, and the consequent remuneration arrangements form a *continuum*, with workers paid through fixed salaries and benefits constituting one pole and freelancers compensated through a larger share of variable revenue forming the other pole. Hagiu and Wright suggest a 'hybrid category', 'dependent contractors' with a different regime than employees/workers or genuinely self-employed for situations such as this, in which the platforms will need to grant some but not all control rights to their workers. The platforms would need to provide to hybrid 'dependent contractors' with a fraction of the benefits normally enjoyed by the traditional employees¹²⁸⁹. The authors note that such a hybrid approach may have positive welfare effects, but there is also the risk that it may lead to a lower payoff to the worker, if the platform switches from the traditional employment model to the hybrid model, as it would retain more of the workers' surplus. This approach may nevertheless offer the necessary degree of flexibility for digital platforms to develop their business model, while offering some limited protection to 'dependent contractors'¹²⁹⁰. The choice between the various options on offer will ultimately depend on the trade-off between the incentives of the platform, and that of the contractors, to innovate, as well as the distributional implications for the workers, whose protection is the purpose of both labour law, as well as competition law, to the extent that monopsony labour power may affect the specific labour market and become a source of bargaining asymmetries.

However we consider that the proposals advanced by some authors to introduce a hybrid category of workers to whom to extend some labour protection,¹²⁹¹ including immunity of the relevant collective bargaining from competition law suffers from various problems and the expansion of the workers' category may be a preferable option. A number of authors, including Countouris and De Stefano¹²⁹² already engaged multiple

times with the shortcomings of these proposals. In particular, legal systems where something along the lines of hybrid categories were introduced experienced increased levels of litigation and uncertainty, caused by the fact that parties had to litigate over three rather than two employment statutes. At the same time, many workers who would have been classified as fully-fledged employees, with access to employment protection in its entirety, had a hybrid category not been introduced, were denied basic employment rights without they being substantially different from traditional employees. No positive effects in terms of innovation, productivity or consumer welfare have been proved to be associated with the past introduction of hybrid categories.

5.2.1.2. Promoting Collective Bargaining for labour and beyond (users)

In *Albany*¹²⁹³ the CJEU clearly took the view that it was ‘beyond question that certain restrictions of competition are inherent in collective agreements between organisations representing employers and workers’. However, it was also willing to concede that ‘the social policy objectives pursued by such agreements would be seriously undermined if management and labour were subject to [EU competition rules] when seeking jointly to adopt measures to improve conditions of work and employment’¹²⁹⁴. This concession was premised on various treaty-based textual justifications but also on the understanding that the ‘nature and purpose’ of the agreement was that of ‘improving ... working conditions, namely ...remuneration’¹²⁹⁵. The CJEU found that, first, the collective agreement at issue was concluded in the form of a collective agreement and was the outcome of collective negotiations between organizations representing employers and workers, and second, its purpose, the establishment of a supplementary pension scheme aiming to guarantee a certain level of pension for all workers in the sector ‘contributed directly to improving one of their working conditions, namely their remuneration’,¹²⁹⁶ consequently excluding this agreement from the scope of Article 101(1) TFEU.

Under the current approach followed by the EU courts, an association acting on behalf of self-employed persons is to be regarded as an association of undertakings under Article 101(1) TFEU¹²⁹⁷. It has become increasingly clear that a) when the self-employed seek to bargain collectively the terms and conditions of their services, or b) where collective agreements concluded by trade unions for subordinate workers also contain minimum labour costs provision that also apply to self-employed workers, then the exclusion from competition law will not apply to such self-employed workers as competition authorities or courts see them as ‘undertakings’.

1293 Case C-67/96, *Albany International BV v Stichting Bedrijfspensioenfonds Textielindustrie* [1999] ECR I-5751.

1294 *Ibid.*, para. 59.

1295 *Ibid.*, para. 63.

1296 *Ibid.*, paras 62–63.

1297 Case C-309/99, *JCJ Wouters, JW Savelbergh and Price Waterhouse Belastingadviseurs BV v Algemene Raad van de Nederlandse Orde van Advocaten*, interveners: Raad van de Balies van de Europese Gemeenschap [2002] ECR I-1577. In *Wouters*, the CJEU examined the compatibility with Article 101 TFEU of a regulation adopted by the Netherlands Bar Association prohibiting lawyers practising in the Netherlands from entering into multi-disciplinary partnerships with members of the professional category of accountants.

As for (a), in *Pavlov*, a collective agreement also setting up a pension fund, but concluded by an ‘organisation ... made up solely of self-employed medical specialists’ did not fall under the *Albany* exception and the organisation was seen as acting as an association of ‘undertakings’ and as such subject to competition law¹²⁹⁸. This was so because ‘the Treaty did not contain any provisions ‘encouraging the members of the liberal professions to conclude collective agreements with a view to improving their terms of employment and working conditions’¹²⁹⁹.

As for (b) in *FNV Kunsten* the Court held that ‘in so far as an organisation representing workers carries out negotiations acting in the name, and on behalf, of those self-employed persons who are its members, it does not act as a trade union association and therefore as a social partner, but, in reality, acts as an association of undertakings’¹³⁰⁰, and is therefore also exposed to the full application of EU Competition law rules. An exception to these rules, the Court said in *FNV Kunsten*, is only possible ‘if the service providers, in the name and on behalf of whom the trade union negotiated, are in fact “false self-employed”, that is to say, service providers in a situation comparable to that of employees’¹³⁰¹. This may require the *Albany* exclusion [to] be rephrased through a functional interpretation of the notion of undertaking in EU competition law. This would support an exclusion for all collective bargaining processes aimed at overcoming economic dependency of economically dependent service providers, irrespective from whether they are self-employed or not.

A broad functional approach that would apply case-by-case may nevertheless raise questions as to the limitations to the category of false self-employed, to the extent that situations of economic and technological dependence may occur in a variety of circumstances and could have a number of sources, depending on the idiosyncratic circumstances of each case, some of which it might be quite difficult for competition law enforcers to evaluate. Hence, a different approach would be not to proceed with a case-by-case multi-factor analysis but with a categorisation approach that would classify certain types of activity as more conducive to be considered as leading to a false self-employed status and specific criteria that if satisfied would establish a rebuttable presumption that the collective agreement was concluded by false self-employed. The latter approach was followed by the Irish legislator in the recent amendment of the Competition Act 2002, which provides that Section 4 of the Competition Act (which prohibits anti-competitive agreements, decisions and concerted practices, similarly to Article 101 TFEU) shall not apply to collective bargaining in respect of a ‘relevant category of self-employed worker’.

More specifically, the Act provides a specific exemption for three named categories of self-employed workers: voiceover actors; session musicians; and freelance journalists. These workers have the right to bargain collectively with employers in relation to working conditions and terms of employment, including pay rates. The Irish Competition Act distinguishes between two relevant categories of self-employed workers that may be

1298 Case C-180/98, *Pavel Pavlov and Others v Stichting Pensioenfonds Medische Specialisten*, ECLI:EU:C:2000:428, para. 72.

1299 *Ibid.*, para. 69.

1300 Case C-413/13, *FNV Kunsten Informatie en Media v Staat der Nederlanden*, ECLI:EU:C:2014:2411, para. 28.

1301 *Ibid.*, para. 31.

able to enter into collective bargaining agreements with employers:

'A *false self-employed worker*' is defined as an individual who

- (a) performs for a person ('other person'), under a contract (whether express or implied and if express, whether orally or in writing), the same activity or service as an employee of the other person,
- (b) has a relationship of subordination in relation to the other person for the duration of the contractual relationship,
- (c) is required to follow the instructions of the other person regarding the time, place and content of his or her work,
- (d) does not share in the other person's commercial risk,
- (e) has no independence as regards the determination of the time schedule, place and manner of performing the tasks assigned to him or her, and
- (f) for the duration of the contractual relationship, forms an integral part of the other person's undertaking

A *fully dependent self-employed worker* is defined as an individual

- (a) who performs services for another person (whether or not the person for whom the service is being performed is also an employer of employees) under a contract (whether express or implied, and if express, whether orally or in writing), and
- (b) whose main income in respect of the performance of such services under contract is derived from not more than 2 persons

The Irish Competition Act puts in place a procedure to apply for the benefit of the exception. Trade unions may apply to the Minister for Business, Enterprise and Innovation to permit groups of self-employed workers falling within these definitions to act collectively. As it is indicated in the amended Competition Act, the onus is on the Trade Union making the application to show that the self-employed workers they represent fall within the above definitions, and to also show that providing the exception (i) '(w)ill have no or minimal economic effect on the market in which the class of self-employed worker concerned operates,, (ii) will not lead to or result in significant costs to the State, and (iii) will not otherwise contravene the requirements of this Act or any other enactment or rule of law (including the law in relation to the European Union) relating to the prohibition on the prevention, restriction or distortion of competition in trade in any goods or services'.

Similar approaches to promote collective bargaining in the context of the digital economy are taking place regarding other segments of the value chain, such as producers of content benefitting from a copyright. One may first refer to the collecting society model, put in place for the collective management of copyright rights by authors and other creatives, which benefitted from a *de facto* or statutory monopoly in each Member State

and whose activities were regulated under domestic legislation and national regulatory measures that widely differed in their approach, at least until the implementation of the 2014 Collective Rights Management Directive¹³⁰². Collecting societies were organised in some Member States more than in others, according to the principle of solidarity, as they required all right holders to pay the same fee for the administration of their rights and relied on cross-subsidisation of the less successful artist by the most successful ones, for instance through the organisation of hardship funds that represented for some collecting societies a substantial amount of transfers for social purposes¹³⁰³. The collecting society model has nevertheless been subject to strict competition law scrutiny and was gradually transformed with the increasing emphasis put, in particular since the Commission's recommendation 2005/737/EC in 2005, on promoting cross-border competition between collecting societies, thus progressively breaking the monopoly positions they benefitted from¹³⁰⁴. The agreements concluded by collecting societies have been since assessed under Article 101 TFEU, in recent years, for several dimensions of their activity¹³⁰⁵.

The recent EU Copyright Directive also promotes collective bargaining as a way to deal with the excessive bargaining power of digital platforms¹³⁰⁶. Article 18 of EU Copyright Directive creates a right to 'appropriate and proportionate remuneration' for exploitation of creative works. According to this provision, in the implementation in national law of this principle, 'Member States shall be free to use different mechanisms and take into

1302 Directive 2014/26/EU of the European Parliament and of the Council of 26 February 2014 on collective management of copyright and related rights and multi-territorial licensing of rights in musical works for online use in the internal market, [2014] OJ L 84/72. The Directive sets out the standards that EU Collective Management Organisations (CMOs) which choose to engage in multi-territorial licensing of online musical rights must meet.

1303 See, the discussion in S. Schroff & J. Street, *The politics of the Digital Single Market: culture vs. competition vs. copyright*, (2018) 21(10) *Information, Communication & Society* 1305, 1317, detailing that in 2011, the German GEMA distributed 5.9% of its distributable income for social purposes, including pensions, hardship funds and promotion, the French SACEM 7% and the Spanish SGAE 9.6%.

1304 Commission Recommendation of 18 May 2005 on collective cross-border management of copyright and related rights for legitimate online music services, [2005] OJ L 276/54.

1305 See, for instance, representation agreements in which a collecting society appoints another society to administer rights on its behalf in a foreign territory, which were scrutinised in the CISAC decision because of territorial restrictions, to the extent that each society can issue licenses only for its own territory and users could only obtain a licence from their local collecting society, as the granted licence was limited to the domestic territory of the collecting society: see European Commission, Case COMP/C2/38.698 – CISAC (2008), available at http://ec.europa.eu/competition/antitrust/cases/dec_docs/38698/38698_4567_1.pdf. However, the EU General Court annulled the Commission's decision, finding that the EU Commission had not prove that the European societies engaged in a concerted practice aimed at restricting competition when they implemented identical territorial restrictions in their reciprocals, as it had no evidence for coordination between societies of the territorial scope of their mandates (i.e. no emails, letters or minutes of meetings). The Commission had also not convincingly rebut CISAC's argument that the existence of similar territorial restrictions (the 'parallel behavior') was not the result of coordination, but had other good reasons for it, such as the fact that protection and enforcement of rights require local presence and that it cannot be assumed that incentives to monitor and enforce rights continue to exist where there is competition between societies. See, Case T-442/08 CISAC v. European Commission, ECLI:EU:T:2013:188.

1306 Directive (EU) 2019/790 of the European Parliament and of the Council of 17 April 2019 on copyright and related rights in the Digital Single Market and amending Directives 96/9/EC and 2001/29/EC, [2019] OJ L130/92.

account the principle of contractual freedom and a fair balance of rights and interests'. Recital 73 of the Copyright Directive states that Member States should be free to implement the principle of appropriate and proportionate remuneration through different existing or newly introduced mechanisms, which could include collective bargaining and other mechanisms, provided that such mechanisms are in conformity with applicable EU law.

Similar mechanisms promoting collective bargaining may also apply with regard to the users of digital platforms, which as explained in a previous Section, contribute to the surplus value generated by the platform, without necessarily being adequately compensated for this contribution. Some authors have suggested to treat the use of a search engine and the facilitation (active or passive) of data harvesting as a form of labour contributing to the surplus value generated by the digital value chain that has to be compensated, also recommending that the users may be organised so as to collectively bargain with the dominant digital platforms in equality of arms¹³⁰⁷. Such collective bargaining would not fall under the scope of competition law if it concerns final consumers, which cannot be considered as 'undertakings', but competition law may apply if the users are intermediary consumers competing in some product market.

5.2.1.3. Designing competition law for the digital labour market

A further option is to re-design the tools of competition law so as to intervene more effectively against labour market power in digital markets. The separate and antagonistic spheres approach followed so far with regard to the interaction between competition law and labour law, led to the conceptualisation of these two areas of law in isolation to each other, competition law applying merely to 'undertakings', while labour law protecting 'workers', with the interplay between the two being conceived negatively as merely ensuring that the aims followed by one will not be jeopardised by the application of the other. This approach may explain why issues of the respective scope of competition law and labour law became the central theme of this interaction, with an attempt to ensure that the application of competition law will not limit the ability of trade unions to collectively bargain with employers and protect the rights of workers.

It is nevertheless possible to adopt a more pro-active agenda in envisioning the relation of competition law and labour, by putting forward the enforcement of competition law, rather than, or in conjunction with, the establishment of exceptions to the enforcement of competition law in order to preserve the possibilities of collective bargaining, in order to deal with the market failures affecting the optimal performance of labour markets and leading to the exploitation of workers, in particular tackle labour market power.

Labour market power has been defined as 'the ability of employers to set wages below workers' marginal revenue product', which denotes the existence of labour exploitation, a concept that has nothing to do with the concept of exploitation employed by the la-

1307 For such a suggestion, see I. Arrieta Ibarra, L. Goff, D. Jiménez Hernández, J. Lanier & G. E. Weyl, Should We Treat Data as Labor? Moving Beyond 'Free' (December 27, 2017). American Economic Association Papers & Proceedings, Vol. 1, No. 1, Forthcoming. Available at SSRN: <https://ssrn.com/abstract=3093683>.

bour theory of value inspiring Marxist approaches, as it only focuses on the exploitation of labour by virtue of the imperfection of the (labour) market¹³⁰⁸. A labour market has been defined as ‘a group of jobs, between which workers can switch with relative ease (for example, computer programmers, lawyers, or unskilled workers) located within a geographic area usually defined by the commuting distance of workers’.¹³⁰⁹ The concept assumes that there exists a ‘spot market’ for labour hours, firms employing a number of workers for a specific amount of hours. Under the profit maximization principle, a firm would employ a number of workers whose net marginal product equals the marginal cost of labour, in terms of wages paid. One may conceive the employment relation as a joint venture between owners of capital and workers to the extent that firms combine labour (L) and capital (K) to produce output (Q). The marginal product of a typical worker varies over time. Joan Robinson employed for her definition of exploitation the ‘marginal physical productivity of labour’, which she defined as ‘the increment of output caused by employing an additional unit of labour with a fixed expenditure on other factors’¹³¹⁰. The employment relationship results in a gap between the workers’ marginal product at the firm and their alternative wage offers (in real terms). According to Robinson, exploitation may occur due to the workers’ weaker bargaining power than the employers’, the ‘fundamental cause’ of exploitation being ‘the lack of perfect elasticity in the supply of labour or in the demand for commodities’¹³¹¹. Exploitation may be monopolistic, if this results from imperfections in the commodities market (even if the labour market is competitive), or monopsonistic, if this is due to imperfect elasticity of the supply of labour (even if the product market is perfectly competitive)¹³¹². In situations of monopsonistic exploitation, the wage would equal the supply price of the employee, which would be inferior, because of imperfect competition, to the value of the marginal physical product of labour. Although a minimum wage would remove this kind of exploitation as well as contribute other tangible economic benefits,¹³¹³ it would also have as an effect to increase production costs, and may lead to a number of negative effects. First, it may increase prices for consumers, if these high costs would be passed on to the consumers in the commodity market, hence workers may lose as consumers more than what can be offset by their gain as wage earners. Second, it may lead to labour factor substitution with a decrease in the level of employment.

As it is succinctly summarised by Marinescu and Hovenkamp the ‘key message from economic theory is that as one moves away from the competitive equilibrium towards a situation of monopsony in the (labour) market, wages and production both generally tend to decrease’¹³¹⁴.

1308 See, J. Robinson, *The Economics of Imperfect Competition* (MacMillan, 1933), 283, noting that ‘a group of workers are being exploited when their wage is less than the marginal physical product that they are producing, valued at the price at which it is being sold’.

Labour market power may have different sources. First, with the rise of economic concentration, it is highly likely that a few firms would operate in a given labour market, that is in a given labour market only one or few employers will be able to hire from the available pool of workers¹³¹⁵, may hold monopsony power. This provides them the power to reduce wages below what the workers would have been paid had the labour market be competitive. The monopsonist may thus enjoy a higher monopsony surplus, reducing by the same the surplus left to labour. This is not just a theoretical possibility as there has been recent empirical research documenting the rise of labour market concentration in the US¹³¹⁶. The result of labour monopsony or more generally labour market power is that the workers are paid below their marginal revenue product. As noted by the latest OECD Outlook 2019 publication, '[w]hile most of this evidence typically refers to employees, there are some studies quantifying the extent to which independent contractors, including platform workers, may be exposed to monopsony power'.¹³¹⁷

Economic concentration in industries or product markets does not always lead to monopsony or oligopsony and labour market power. There are a number of market characteristics to take into account requiring some elaborate analysis of the interplay of supply (of labour) and demand in the specific market. One may use the hypothetical monopolist test (or Small Significant and Non transitory Increase in Price Test or SS-NIP) which is adopted by the European Commission's Notice on Market Definition for product markets¹³¹⁸. This typically aims to measure cross-price elasticity between two products through a speculative experiment postulating a hypothetical small but lasting change in relative prices [5-10%] and evaluating the likely reactions of customers to that increase. The important parameter that such a test enables us to observe is the

1316 See, J. Azar, I. Marinescu & M. Steinbaum, *Labour Market Concentration*, IZA Institute of Labour Economics (December 2017), available at <https://www.econstor.eu/bitstream/10419/177058/1/dp11254.pdf> (documenting labour market concentration for over 8,000 geographic-occupational labour markets in the US and finding that the average market is highly concentrated, this concentration being associated with a 17% decline in posted wages, therefore suggesting that concentration increases labour market power). These results were supplemented by a subsequent study exploring estimates of labour market concentration to cover almost all online job postings in the United States for the year 2016 compiling an HHI (Herfindahl-Hirschman index) for each commuting zone by 6-digit SOC occupation: J. Azar, I. Marinescu, M. Steinbaum, B. Taska, *Concentration in US Labor Markets: Evidence from Online Vacancy Data* (August 10, 2018). Available at SSRN: <https://ssrn.com/abstract=3133344> (finding that the average labour market has an HHI of 4,378, or the equivalent of 2.3 recruiting employers and that 60% of labor markets are highly concentrated (above 2,500 HHI). The HHI is a concept developed by economists and used by many competition authorities as a screen to assess likely market power of two or more merging firms. It is derived by adding the square of the market share of every firm in the market. This emphasises the importance for competition by the larger firms.

1317 OECD, *Employment Outlook 2019*, (Paris, 2019), p.154, referring in particular to the studies by Dube et al. 'Monopsony in Online Labor Markets', *American Economic Review: Insights* (forthcoming) providing evidence that workers on Amazon Mechanical Turk can have a residual labour supply elasticity as low as 0.1, while Chevalier et al. 'The Value of Flexible Work: Evidence from Uber Drivers', *Journal of Political Economy* (forthcoming) find values comprised between 1 and 2 for Uber drivers.

1318 Commission Notice on the definition of relevant market for the purposes of Community competition law, [1997] OJ C 372/5.

price elasticity of demand facing the hypothetical monopolist: if the demand is elastic, then it would not make sense for this monopolist to implement profitably the SSNIP and therefore the relevant market needs to be broadened; if the demand elasticity is low, then it would be profitable for the monopolist to implement the SSNIP, and therefore the relevant market should be narrowed down. In our context, the test should be adjusted for gauging monopsony labour power. Hence, it will explore the hypothetical monopsonist's ability to impose a 'Small Significant Non-transitory Reduction in Wages' (SSNRW test) looking to the elasticity of labour supply in the hypothetical market¹³¹⁹. The geographical dimension of these labour markets may be determined according to some evidence on work commuting. For instance, Marinescu and Hovenkamp suggest the use as a starting point in the analysis for geographic markets of 'Observed Commuting Zones (CZs)', which are 'geographic area definitions comprising clusters of counties that were developed by the United States Department of Agriculture (USDA) based on data from the 2000 Census on commuting patterns across counties to capture local economies and local labour markets'¹³²⁰. With regard to product markets, they suggest the use as a starting point of the analysis of six digits Standard Occupational Classification (SOC) codes and a job title (e.g. senior as opposed to junior accountant), which may define markets by occupational category¹³²¹. The purpose of this test and of the market definition exercise in general is to determine, indirectly, the existence of labour market power. The competition authority may compile market shares in these labour markets and determine if a specific undertaking or undertakings hold a dominant position or more generally market power.

However, in the context of labour markets, concentration is not always a necessary condition for the finding of labour market power. This is because there may be different sources of labour market power, such as product differentiation and search frictions¹³²². These may be particularly strong in some cases, for instance because of the absence of other economic activities in the specific region and the dominant presence of one employer, so that even an individual firm may be considered as an antitrust labour market¹³²³. The difficulties of people to move in different places to search for work because of personal attachments (family, friends or local community), language and cultural factors, economic factors (such as a mortgaged home) also indicate that it is not possible to purely and simply transpose to labour markets the assumptions driving the assessment of market power in product markets (and in particular the baseline assumption of perfect competition). Hence, it is important to stay open to the idea that there may exist labour market power even in non-concentrated labour markets. The difficulty in

1319 For a detailed analysis, see M. Steinbaum, *Antitrust, the Gig Economy, and Labor Market Power* (June 12, 2019). 1323 M. Steinbaum, *Evidence and Analysis of Monopsony Power, Including but not limited to, in labour markets*, Roosevelt Institute (August 2018), available at <file://ad.ucl.ac.uk/homea/uctlio/ Documents/ftc-2018-0054-d-0006-151013.pdf>.

this case would be for competition law to develop adequate metrics so as not for these instances of labour market power to escape the scrutiny of competition authorities.

A possible option is to rely on a multi-factor analysis that would take into account different sources of evidence of labour market power/monopsony. First, employers with labour market power are able to impose to workers adverse conditions on employment. These can take the form of non-compete clauses which go beyond what is necessary to protect the transfer of know-how to the worker, other disadvantageous terms (such as longer working hours, mandatory arbitration and class action waivers or broad non-disclosure agreements) without compensation, deferred compensation agreements or any other working conditions that depart from the norm in the specific industry or more broadly. Although the analysis may in some instances require to first look to 'abnormal' conduct or performance before addressing the issue of the market structure, thus inverting the traditional approach in determining the existence of market power, it is not unprecedented¹³²⁴. Second, Steinbaum puts forward as evidence of labour market power 'the prevalence of earnings inequality between similar workers who work at different firms in the same (labour) market' to the extent that in 'a competitive labor market, the existence of outside job offers at the market wage makes the (labour) supply curve infinitely elastic to individual firms' and '(a)ny worker paid less than they are worth would leave for a better offer'¹³²⁵. Another source of direct evidence of labour market power is when 'quits do not correspond very much to wage changes', this evidence being easier to comply in the context of digital labour platforms (such as Amazon Turk) where tasks and workers tend to be homogeneous and therefore easily comparable¹³²⁶.

Hence, it has been suggested that policy-makers develop a broader list of criteria to take into account in defining the existence of labour market power. These recommendations include the following:

- a (rebuttable) presumption that 'a market share of over 50% of employment (or alternatively, of posted job vacancies) in a well-defined antitrust (labour) market' may constitute evidence of market power';
- '(t)he ability to lower wages below what would be charged in a competitive market';

1324 It is indeed possible that economic methods may be used to assess market power directly by focusing on changes in market power, examining for instance a historical counterfactual without the challenged practices in order to decide if a conduct has increased market power (a retrospective analysis in the situation of an agreement or abusive conduct), or providing an analysis of the change in incentives (a prospective analysis for instance regarding mergers) in order to examine if the conduct is likely to increase market power. Profitability analysis or the fact that there has been permanent price discrimination or price stability can also be used as factors, among others, enabling competition authorities to infer the existence of market power. For a discussion, see JB Baker and T Bresnahan, 'Economic Evidence in Antitrust: Defining Markets and Measuring Market Power', in Paolo Buccirossi (ed.) *Handbook of Antitrust Economics* (MIT Press, 2008), 1.

1326 Ibid.

- '(t)he ability to wage-discriminate, that is, to pay similar workers working in the same market significantly different wages';
- '(t)he ability to impose disadvantageous nonwage contractual terms on workers without compensation'¹³²⁷.

One may also argue for the analysis of the superior bargaining power of some employers, in view for instance of significant investments made by the workers for their education and training for the specific job, which make it quite difficult for them to switch if these costs are non-recoverable in their new job or occupation. In some economic sectors (for instance the fashion industry) working for a specific undertaking may also provide an important quality certification to the worker in terms of status and prestige in the profession, which it would be difficult to get elsewhere, thus further limiting the available options of employment to workers and their incentive to switch and by the same providing labour market power to the specific employer. Although situations of economic and technological dependence may not provide any interesting insights as to the existence of labour market power for workers in employment contracts and thus integrated to the undertaking, they may be significant factors to take into account when considering conduct involving gig workers or self-employed that may be qualified as separate undertakings under EU competition law.

Developing new concepts in order to gauge labour market power is not the only reform to undertake. It is also crucial to reflect on specific antitrust theories of harm and metrics that would fit the goal of protecting labour from the negative effects of monopsony. Such theories of harm would apply across the various areas of competition law, in the assessment of anticompetitive collusion, abuse of dominance or merger control. Reducing wages obviously constitutes a prevalent theory of harm in this context. This may result from various types of conduct: horizontal cartel-like conduct, such as non-poaching agreements¹³²⁸, or supplier wage suppression the monosponist orchestrating

Duke University and Duke University Health System*, <https://www.justice.gov/atr/case/danielle-seaman-v-duke-university-et-al> and various class actions brought by private plaintiffs, in particular *In re: High-Tech Employee Antitrust Litigation* (N.D. Cal. No. 11-CV-2509-LHK) regarding agreements between the executives of Adobe Systems, Apple, Google, Intel, Intuit, Lucasfilm, and Pixar to eliminate competition among them for skilled labour which was settled in September 2015 for \$415 million (see, <https://www.reuters.com/article/apple-google-ruling/u-s-judge-approves-415-mln-settlement-in-tech-worker-lawsuit-idUSL1N11908520150903>). In Europe,

cartels between suppliers to reduce the wage of their workers and then pass on some of the savings to the monopsonist upstream¹³²⁹. Some of these theories of harm are more speculative¹³³⁰. For instance, predatory hiring as an abuse of a dominant position where the incumbent monopsonist raises wages above the workers' marginal revenue product in order to exclude a new competitor from the market, as this would not be able to make profits and following the exit of the competitor the incumbent would be able to reduce wages below the workers' marginal revenue product¹³³¹.

Merger control will certainly become an important area of competition law enforcement regarding the effect of mergers (horizontal or vertical) on labour markets. One may expect the application of unilateral non-coordinated theories of harm in the context of horizontal mergers (mergers between competitors). Simply put, a horizontal merger reduces competitive rivalry to the extent that the target company exert a competitive constraint. Furthermore, other competitors benefit from the fact that the merged entity behaves less competitively than the two merging firm would have done absent the merger in question. The decision of the firms to increase prices following the merger, is motivated by the fact that part of the loss in sales is being captured by (diverted to) the other merging firm. Therefore, the closer are the substitute products of the merging firms, the stronger is the incentive of the merged entity to increase prices. Similar analysis may be performed as to the incentive of the merging firms to reduce wages, if the two merging firms were close competitors in labour markets. An interesting concept suggested in the context of merger control to estimate this unilateral effect is that of 'Downward Wage Pressure' (DWP) which aims to measure the effects of a merger on the wages of the workers in the labour markets affected. This concept/metric is analogous to the 'Upward Pricing Pressure' (UPP) that is used in merger control to determine the extent to which a merger and the consequent removal of a competitive constraint will alter the margins of the merging firms, the elimination of competition between the merging firms generating upward pricing pressure as the merging firm will be able to internalise the profits on sales diverted to what would be now a part of the same undertaking. UPP also takes into account the merger-specific efficiency improvements which may tend to offset the upward pricing pressure. DWP may be inspired by similar principles¹³³². However, labour theories of harm may not only be take the form of lower wages, but may also relate to the quality of the employment relation, the ability of workers to benefit a fair share from increases in their productivity, because of innovation, thus affecting their incentives, and other anticompetitive strategies that may affect the share of the

the Italian competition authority (AGCM) fined eight modelling agencies a total of €4.5 million for wage fixing agreements: see <https://www.agcm.it/media/comunicati-stampa/2016/11/alias-8448>. The UK CMA imposed fines totalling £1,533,500 on 5 model agencies for colluding instead of competing on prices for modelling services: <https://www.gov.uk/government/news/model-agencies-fined-15-million-for-price-collusion>.

gains accruing to workers (as opposed to management and investors).

There is still little experience among competition authorities with assessing the effects of a restriction of competition on labour market. There is however some interesting experience in South Africa about the effects of mergers on employment, as part of the public interest test adopted under South African competition law¹³³³. There is case law under South African competition law on merger specific retrenchments¹³³⁴, which also proceeds to an analysis of alternative employment opportunities for the workers that were fired as a result of the merger. Including employment considerations in the analysis, in addition to concerns over wage reductions and restrictions on the conditions of employment, will require a broader standard that would be closer to a public interest one. In any case the emphasis that this rapidly developing competition law literature puts on the anticompetitive effects on labour markets already breaks with the narrow vision of consumer welfare standard and the emphasis on product markets that has prevailed so far in competition law. This raises interesting questions as to a more optimal and complementary relation between competition law and labour law.

In conclusion, new competition law concepts and metrics and the way protection of labour considerations can be integrated in the current competition law framework constitutes a fertile area for future research.

5.2.1.4. Competition law and blockchain technology: defining economic activity and regulatability issues

Determining if an entity engaging with some blockchain-related activity is an undertaking may be a relatively simple exercise. If, one takes the example of collusion managed or facilitated by decentralized ledger technology (DLT), it will all depend on the activity of the owners of the nodes (e.g. any active electronic device connected to the Internet and disposing of an IP address) supporting the network by maintaining a copy of a blockchain and eventually processing transactions. To the extent that the owners of the nodes willingly contribute their computing resources to store and validate transactions, earning a transaction fee or a reward in the native token of the specific blockchain, they exercise an economic activity. EU case law accepts that even if the activity is non-profit, it could still be considered as an economic activity if it has the potential to be 'at least, in principle' exercised by a "private undertaking in order to make profits"¹³³⁵.

1333 For an excellent discussion, see A. Raslan, *Mixed Policy Objectives in Merger Control: What Can Developing Countries Learn from South Africa?* (2016) 39(4) *World Competition* 625.

1334 To be distinguished from operational employment loss, which is dealt under labour law, although the distinction is not always easy to make.

1335 See *Joined Cases C-264/01, C-306/01, C-354/01 and C-355/01, AOK Bundesverband and others* [2004] ECR I-2493, Opinion of AG Jacobs, [27]. For an example see *Case C-437/09 AG2R Prévoyance v Beaudout Père et Fils SARL* [2011] ECR I-973.

Brazil is the only BRICS country that is currently investigating a blockchain related case. There is currently a unilateral conduct investigation regarding exclusionary practices by traditional banks against emerging technology companies (fintechs). The case is still under analysis by CADE.

Source: BRICS NCAs Questionnaire.

The absence of a profit-motive does not mean that the entity does not exercise an economic activity. EU competition law does not make any distinction between altruistic entities and entities motivated by profits, as in both cases it is possible that the specific conduct reduces competition and/or welfare regardless of the motives and preferences of the producers. A similar conclusion may be reached if one examines the activity of other intermediaries of the blockchain, such as oracles, digital wallets, digital exchanges, DApps providers, or even Blockchain as a service ('BaaS') providers. However, it is also possible that the blockchain activity may not be qualified as economic, if, for instance, it relates to 'the exercise of official authority'¹³³⁶, for instance the establishment of a public land registry using blockchain technology even if access to the public database (the registry) is provided in return for remuneration¹³³⁷, or if it is related to an exclusively social function based on the principle of 'solidarity', such as a blockchain operating in a compulsory sickness insurance scheme in order to ensure transparency and reduce the opportunity of fraud¹³³⁸.

Blockchain may also curtail the ability of competition regulators to identify the entities that would be liable for competition law infringements and to adopt appropriate remedies and sanctions. At the early stages of the development of the Internet, the thesis of the 'unregulatability' of the Internet was refuted by authors claiming that there were clearly points of control and entities that could be held liable for the risks their activity contributed in surging¹³³⁹. Like the Internet, blockchain is borderless, but crucially it is decentralized, which makes it difficult, in particular if the activity takes place in the context of public permissionless blockchains, to determine who should bear the responsibility for the social costs and the private harms generated by the blockchain-related activity. A distributed ledger may need forms of 'distributed liability': "all entities in the system need to consider contingent liability risk"¹³⁴⁰. Should that extend to all the blockchain participants, irrespective of their governance roles, or only to those that exercise a significant influence on the activity that led to the specific social costs or to the specific private harm to be compensated? And if the option of collective responsibility is finally chosen, how would this be apportioned between the various nodes, to the extent that

1336 See Case C-343/95 *Diego Cali & Figli Srl v Servizi Ecologici Porto di Genova Spa* [1997] ECR I-1547; Case C-364/92 *SAT Fluggesellschaft mbH v Eurocontrol* [1994] ECR I-43; Case C-138/11, (258).

1337 This was not considered by the CJEU as sufficient on its own right for the activity carried out to be classified as an economic activity, as its payment was laid down by law and not determined, directly or indirectly by that entity: see Case C-138/11, (258), [39] and [42].

1338 See Joined Cases C-159/91 and C-160/91 *Poucet and Pistre v v AGF and Cancava* [1993] ECR I-637; Case C-437/09, (261).

1339 See Jack Goldsmith and Tim Wu, *Who Controls the Internet? Illusions of a Borderless World* (Oxford University Press, 2006), cited by De Filippi and Wright, (21), 50.

1340 See Zetzche et al., (285), 9.

node owners in a permissionless blockchain may not even be aware of the specific conduct, or on who were the other node owners involved. Zetsche et al. emphasize the governance structure of the DLT system, noting the existence, in most DLT projects, even permissionless blockchains, of a 'DLT hierarchy' consisting of the following groups:

- (i) "the core group that sets-up the code design and (*de facto*) governs the DLT, for instance by having the technical ability and opinion leadership to prompt a hard fork of the system (under certain conditions);
- (ii) the owners of additional servers running the distributed ledger code for validation purposes [...];
- (iii) qualified users of the distributed ledger, such as exchanges, lending institutions, miners etc.; and
- (iv) third parties affected by the system without directly relying on the technology, for instance, [...] simple users, clients of intermediaries [...] etc."¹³⁴¹.

Some of these blockchain participants, but not all, may be qualified as undertakings, in that they offer goods and services on a market. For instance, it is clear that category (iv) will most likely comprise end users or consumers that do not offer products or services on a market and, therefore, will not be qualified as 'undertakings'. Of course, being a natural person does not exclude *ipso facto* the possibility of being qualified as an 'undertaking' if that person exercises an economic activity and does so independent of the power or influence exercised by the specific natural person in the governance of the DLT. For instance, it is likely that the members of the core group will not be qualified as undertakings in the case that they are employees, who they lead their DLT activity outside their normal working hours and without supervision of their employer, on a voluntary basis. In any case, it becomes crucial to identify the entities that form part of, at least the first four groups of the DLT hierarchy, before determining the governance structure of the DLT.

Determining the 'entity' to be held liable for the competition law infringement presents, however, more difficulties due to the decentralized nature of the blockchain.

The concept of 'control' plays an important role in the process of defining the scope of the competition law intervention against an 'economic entity'. It determines the tangible or intangible assets that constitute the core of the 'undertaking', defines its boundaries and are thus presumed to be under the authority of the undertaking's agents, which may engage through anticompetitive strategies the undertaking's liability¹³⁴². Under the 'single entity doctrine', several legal persons may form an 'economic entity' if a control relationship exists between them, the application of the doctrine presupposing the exercise of 'control' or 'decisive influence'¹³⁴³.

¹³⁴¹ Ibid, 22.

¹³⁴² Case 170/83, Hydrotherm Gerätebau GmbH v Compact del Dott. Ing. Mario Andreoli & C. Sas. [1984] ECR 2999.

¹³⁴³ See, inter alia, Case C-97/08 P, Akzo Nobel and Others v Commission [2009] ECR I-8237; Joined Cases C628/10 P and C14/11 P Alliance One International and Standard Commercial Tobacco v Commission and Commission v Alliance One International and Others, ECLI:EU:C:2012:479, [46]-[47], with regard to the liability of a parent company for the conduct

Should an entity, such as a mining pool, a blockchain intermediary or an intermediary or platform off-blockchain, take control of the blockchain, and the existence of 'control' will have to be determined according to the specific consensus protocol utilized by the blockchain (and if this is based on PoW, PoS or something else), then it may be considered as reasonable to hold this entity liable for anticompetitive conduct perpetrated in the context of the specific blockchain. The same deterrence reasons that have so far justified the liability of parent companies for the anticompetitive activity of their subsidiaries may also operate in this case¹³⁴⁴. However, this expansion of the personal scope of liability has also been criticized¹³⁴⁵. The discussions over the boundaries of the 'single entity' doctrine constitute a specific facet of the broader debate over 'enterprise liability' versus business participant liability, and over when the corporate veil should be pierced¹³⁴⁶.

This discussion is indirectly related to the debate about the boundaries of the 'firm' in economics, with a number of approaches glossing over Ronald Coase's seminal, but incomplete from a descriptive perspective, distinction between 'markets' and 'hierarchies'¹³⁴⁷. The discussion over the boundaries of the firm has also caught the attention of blockchain experts, who rightly observe that blockchain technology contributes to the 'hollowing out' of the firm as initiated by the digital revolution¹³⁴⁸. It is expected that blockchain technology will challenge the 'efficiency' justification for establishing centralized islands of authority (as this is put forward by the proponents of the TCE/contractual theory approach) whilst also enabling a wider distribution of entrepreneurial finance through its distinctive way of attracting finance, the ICO. 'Hollowing out' the firm does not, however, necessarily imply a corresponding growth of the sphere of activities organized through markets to the extent that the dominant strategy of blockchain develop-

of its wholly-owned subsidiary or on which it exercises a decisive influence; Art. 3(2) & 3(3) of Council Regulation (EC) No. 139/2004 on the Control of Concentrations Between Undertakings, OJ 2004 L 24/1 (in the context of merger control).

1344 C. Koenig, *An Economic Analysis of the Single Economic Entity Doctrine in EU Competition Law*, (2017) 13(2) *Journal of Competition Law and Economics*, 281-327.

1345 For a criticism of this case law, see A. Kalintiri, *Revisiting Parental Liability in EU Competition Law*, (2018) *European Law Review*, 145, noting that it may deprive undertakings of the protection afforded to them by the Charter of Fundamental Rights and the general principles of EU law.

1346 For a discussion, see E. Orts, *Business Persons – A Legal Theory of the Firm* (Oxford University Press, 2013).

1347 R. Coase, "The Nature of the Firm", (1937) 4(16) *Economica*, 386. Williamson added 'hybrids': O. Williamson, *The Mechanisms of Governance* (Oxford University Press, 1996). Some approaches explain the emergence of firms, and their boundaries, by transaction costs economics ('TCE') and more broadly contractual theories of vertical integration (see, inter alia, O. Williamson, *The Economic Institutions of Capitalism* (Free Press, 1985); P. Joskow, "The New Institutional Economics: Alternative Approaches", (1995) 151(1) *Journal of Institutional and Theoretical Economics*, 248). Others focus on property rights, by identifying the allocation of residual decision rights with the ownership of the assets of the firm (tangible and intangible) O. Hart & J. Moore, *Property Rights and the Nature of the Firm*, (1990) 98 *Journal of Political Economy*, 1119. Others take an agency perspective, defining the firm as 'a nexus of agency relationships including managerial lines of authority, employment and structures of governance': Orts, 13. A more dynamic perspective views the boundaries of a firm as related to its strategy to leverage its internal capabilities in related markets or to exploit its superior management capabilities and resources: Wernerfelt, 171.

1348 C. Mulligan, *Blockchain Will Kill the Traditional Firm* (imperial.ac.uk, 16 October 2017), <<https://www.imperial.ac.uk/business-school/knowledge/finance/blockchain-will-kill-the-traditional-firm/>>.

ers and intermediaries may be to build ‘walled gardens’ and to architecture eco-systems that could progressively lead to some form of centralization. In this context, determining the entity that could be found liable for a competition law infringement might be an easier task.

Note that, in contrast to the functional approach of EU competition law in defining an undertaking, US antitrust law applies, in principle, to ‘persons’, the concept being broad enough to cover entities having various forms without being necessary to define *ex ante* if the specific entity exercises an economic activity. The term ‘person’ is defined in Section 7 of the Sherman Act as including “[...] corporations and associations existing under or authorized by the laws of either the United States, the laws of any of the Territories, the laws of any State, or the laws of any foreign country”, hence, adopting a purely organic definition of the concept, which contrasts with the functional definition of the concept of ‘undertaking’ in EU law. In the absence of a centralized entity or fiduciary, to which liability for the competition law infringement may be ascribed, it may be difficult to determine the ‘person’ subject to the scope of the Sherman Act.

The knowledge about the governance structure of the DLT may assist regulators and competition authorities in deciding to expand, or not, the scope of liability to all DLT participants, even if they have not actively contributed to the governance of the blockchain. Legal fictions, such as the concept of ‘business networks’ may provide the conceptual framework to expand the scope of liability beyond the confines of pure ‘enterprise liability’, in order to also include entities that facilitated and/or took advantage of the activities assisted by the DLT in their own economic activity, such as the owners of nodes and qualified users. These can be various forms of blockchain participants, such as code developers (for blockchain-based protocols and smart contracts), miners, oracles, digital exchanges and wallets, information intermediaries, hardware manufacturers (in particular, for the IoT) and other commercial operators interacting with the blockchain system¹³⁴⁹.

However, one should be careful before expanding the scope of liability too far, in view of the principle of personal responsibility for infringements of competition law¹³⁵⁰ and the requirements of the European Convention on Human Rights (‘ECHR’), notably the presumption of innocence¹³⁵¹.

1349 The various layers of blockchain technology that may be subject to regulation are discussed in De Filippi and Wright, (21), 184-187.

1350 This principle explains why some fault or negligence is usually required for holding an undertaking liable for infringing competition law. The case law of the EU courts also requires, in case the conduct to which the undertaking contributed is found to be an infringement of competition law results from some collective activity with other undertakings, that the ‘undertaking in question was aware of the offending conduct of the other participants or that it could reasonably have foreseen it and that it was prepared to take the risk’: Case T-410/09 *Almanet v. Commission*, ECLI:EU:T:2012:676, [153] (emphasis added). According to the General Court, what counts is the intention of the undertaking to “help bring about the infringement as a whole”: *Ibid.* Although this case law concerns the concept of ‘single overall agreement’, in my view it shows the importance of the principle of personal responsibility in EU competition law.

1351 The jurisprudence of the EU Courts is constrained by the presumption of innocence, or the principle in *dubio pro reo* (literally: ‘when in doubt, in favor of the accused’), enshrined in Article 6(2) of the European Convention of Human Rights and Article 48(1) of the Charter of Fundamental Rights of the European Union, which requires that “any doubt in the

Deciding on how wide this liability net should extend depends on a first-principles analysis of the values of the specific enforcement system: corrective justice or economic efficiency and the least cost-avoidable principle. These first principles will influence the conceptualization of the causal link that would be required to ascribe liability to a specific entity, from the various groups listed above. One may expect the development of standards reflecting social values and concerns with regard to the allocation of risks and responsibilities, once the technology and governance structure of DLT becomes more widely understood by courts and policymakers. This may lead to different choices. A corrective justice perspective focusing on deterrence, will insist on the liability of any entity that may have contributed with its actions or omissions to the social harm. An efficiency perspective on the basis of the least cost avoidance principle will focus on the liability of the core group of developers in view of their crucial role in the design of the governance of the system¹³⁵². Others may focus on engineering the right incentives for key blockchain participants, for instance by extending liability to miners or owners of the nodes, in view of their crucial role in the operation of the DLT.

The type of sanctions and remedies that may be imposed in the event of competition law infringement is also a matter for further analysis. Individual sanctions may constitute the best option, for instance imposing a fine to the core developers. Remedies may also raise different challenges. Behavioral remedies will require a continuous supervision by the competition authority of the operation of the blockchain, which, in view of the fact that it is public and transparent, may be more easily implemented than behavioral remedies imposed against centralized platforms, which have led to a quite cumbersome process because of the mistrust between the competition authority and the undertaking controlling the platform with regard to the accuracy of the information provided to the authority. Structural remedies may be more difficult to design in view of the lack of clear points of control on which the competition authority may act, for instance by ordering divestiture and other conventional structural remedies. It is more likely that the competition authorities will adopt a mechanism design approach taking into account the complex system of incentives in operation in blockchains to promote competition-compatible blockchain architectures.

5.2.2. The material scope of competition law: filing the jurisdictional gaps of merger control

Most jurisdictions use a bright-line test based on certain turnover thresholds in order to trigger the application of merger control and corresponding duties of prior notification. As the EU Jurisdictional Notice points out the turnover is used as a proxy for the

mind of the Court must operate to the advantage of the undertaking to which the decision finding an infringement was addressed", in particular for decisions imposing fines or periodic penalty payments: see, Case T-44/02 *Dresdner Bank AG and others v. Commission* [2006] II-3567, [60]-[61]; Case T-36/05, *Coats Holdings Ltd v. Commission*, [2007] ECR II-110, [69].

1352 According to the cost-avoidance principle, responsibility should be imposed on the person best placed to avoid the loss most cheaply.

economic resources being combined in a concentration and is allocated geographically in order to reflect the geographic distribution of other resources¹³⁵³. Other jurisdictions, adopt a mixed approach combining turnover thresholds with market shares. In UK merger law, there are two alternative rules setting out the dimensional threshold beyond which a merger qualifies for review, specifically: (i) either the UK turnover of the target firm exceeds £70 million ('the turnover test'); or (ii) the merged entity has a market share of at least 25 per cent and the merger must also result in an increment to that market share ('the share of supply test'. Turnover thresholds may not be adequate in the digital economy, as many merger transactions involve start-ups, which may not have yet commercialised a product or the size of their turnover is relatively small, and not representative of their competition potential, in particular if they have developed innovative technologies, either protected by IP rights/trade secrets or protected by lead time, or hold valuable data. This requires reforms in the scope of merger control.

The European Commission has been envisaging changes to the turnover thresholds, as concerns have been raised periodically, especially in relation to transactions that include large companies in the digital and pharma sectors which, however, do not meet the threshold requirements and therefore escape the Commission's scrutiny. In this respect, the Commission recently launched a consultation on 'procedural and jurisdictional aspects of EU Merger Control'¹³⁵⁴, which proposes the introduction of a deal-size threshold in the EUMR to capture significant acquisitions where the target does not meet the current turnover-based thresholds. This is particularly relevant for innovative markets where commercial success rests on the ability to achieve a critical mass of users, so that the value of the target company depends more on the growth expectations in the long-term base rather than short-term revenue per user. The consultation follows a number of comments by Commissioner Vestager¹³⁵⁵.

This raises an important debate as to the different types of 'local nexus' requirement. One may suggest the development of industry specific criteria, for instance for pharma transactions (where patents issued or applied for may offer a more appropriate threshold) and digital services (where data volumes may be used), although transactions involving the digital economy cannot be reduced to a specific sector. Another possibility is to introduce a threshold based on deal value. This is an approach followed in the recent amendments of German and Austrian competition law.

Under the new German law, the 'value of the consideration paid in return for the trans-

1353 Commission Consolidated Jurisdictional Notice under Council Regulation No 139/ 2004 on the control of concentrations between undertakings [2008] OJ C 95/ 1, para 124.

1354 See European Commission, 'Consultation on Evaluation of Procedural and Jurisdictional Aspects of EU Merger Control' (07 October 2016– 13 January 2017), available at ec.europa.eu/competition/consultations/2016_merger_control/index_en.html

1355 See her criticism of the Facebook/ WhatsApp merger, Margrethe Vestager, EU Commissioner, 'Refining the EU Merger Control System', Speech, Brussels (10 March 2016), suggesting reviewing the notification threshold system as the acquisition was valued at approximately 22 billion dollars. Vestager suggested a system where additional factors, such as deal value or impact on innovation, should form part of the notification threshold. This merger was not caught under the turnover threshold of the EUMR, but was eventually assessed by the Commission as a result of a case referral.

action' will include all consideration paid for the assets and any other consideration of monetary value that the acquirer receives from the seller in connection with the transaction, including any liabilities assumed by the acquirer¹³⁵⁶.

The German explanatory memorandum clearly states that milestone payments and consideration based on earn-out clauses etc. also have to be taken into account when calculating the value of the transaction. The exact calculation of the value of the transaction, however, – in particular with regard to milestone and royalty payments – is hotly debated. Based on our experience in one of the first merger control proceedings concerning the new value-based filing threshold, the Bundeskartallamt takes into account the so-called net present value ('NPV') with regard to earn-out payments (including milestone payments) – i.e. the Bundeskartallamt considers the time value of money.

The 'value of consideration paid in return for the transaction' is not defined under the Austrian draft law, but the explanatory memorandum uses wording similar to that of the German amendment.

The FCO has indicated in the above mentioned precedent that there are strong indications for 'significant activities in Germany' if it can be expected that the German turnover of the target will exceed EUR 5 million in the current business year.

Please note, however, that both the calculation of the value of consideration as well as the requirement of significant domestic activities under the new German and Austrian merger control law has to be assessed on the merits of each individual case.

(Please see Annex 4).

5.2.3. The geographic scope of substantive competition law and remedies

While at the end of the 1970s only nine jurisdictions had a competition law, and only six of them had a competition authority in place, more than 120 jurisdictions around the world have adopted and effectively implement competition law.¹³⁵⁷ The last few decades there has been a considerable increase in the activity of new competition authorities, in the area of merger control but also beyond.¹³⁵⁸ The more authorities are involved in reviewing global merger transactions or are investigating global cartels, the more the complexity of bilateral or multi-lateral co-operation becomes necessary. It is frequent that the same transaction will be reviewed by more than a dozen competition authorities around the world.

This proliferation of national competition laws sets important challenges for the global governance of competition law enforcement in particular for the digital economy, many markets being of a global dimensions. By global governance we refer to the management of the risks generated by the increased interconnectedness of cross-border en-

1356 Section 38 (4a) ARC

1358 Ibid.

forcement of competition law. An important risk involves the costs of ‘cross-jurisdictional disagreement’ which, it is alleged, may create particularly complex situations for international businesses.¹³⁵⁹ These disagreements may also affect the effectiveness of competition law enforcement, as it is increasingly more difficult for competition law regimes to impose remedies that take into account the negative externalities imposed by the specific anticompetitive conduct, not only to their own consumers and economic actors, but also to the consumers and economic actors in other jurisdictions. For instance, a global merger may affect the market of a handful of jurisdictions, each having the possibility to block it, in case of course it has a sufficient size to affect the incentives of the merging firms. As no jurisdiction controls more than 20% of the global GDP, it looks likely that if one jurisdiction takes a decision on the basis of its domestic concerns, this may potentially produce important externalities to the consumers of the other jurisdictions. It is also clear that decisions to block or clear a merger are not ‘symmetrical’: for a global merger to go through it needs the agreement of more than 4 or 5 jurisdictions, while for a global merger to be blocked, the opposition of a significant jurisdiction in terms of global GDP may be sufficient, the stricter substantive standard usually prevailing.¹³⁶⁰

The starting point for our discussion of the mechanisms put in place to deal with inter-jurisdictional tensions should be to define the meaning of ‘jurisdiction’. Jurisdiction can be defined as the government’s general power to exercise authority over all persons and entities within its territory. We generally distinguish three forms of jurisdiction: prescriptive jurisdiction (which refers to the ability of a State to create, amend or repeal legislation, in our case applicable substantive competition law), adjudicative jurisdiction (which consists in the power of a court to hear and resolve legal and factual issues under substantive legal rules and to provide the adjudicative and remedial forum to resolve disputes over rights) and enforcement jurisdiction (the state’s right to enforce this legislation through, for example, the public prosecutors or in our case competition authorities, by investigating an infringement of its laws and punishing the infringers).

The extraterritorial enforcement of competition law (prescriptive jurisdiction) has been a contentious issue, with various approaches tried by several jurisdictions. Most jurisdictions now embrace different versions of the qualified effects doctrine, initiated by Judge Learned Hand in the US *Alcoa* litigation and its progeny¹³⁶¹. In the context of the recent

1359 Ibid., p 39.

1360 Ibid., p 43.

1361 U.S. v. Aluminium Co. of America (Alcoa), 148 F.2d 416, 444 (2nd Cir, 1945), by Judge Learned Hand. See also Hartford Fire Insurance Co. v. California, 509 U.S. 764 (1993) referring to the conduct’s “substantial and intended effect” in the United States as the test to consider. The Foreign Trade Antitrust Improvements Act of 1982 (FTAIA) added a Section 6a to the Sherman Act and a Section 5(a)(3) to the FTC Act, with the aim to clarify the application of US antitrust law to conduct involving only non-import commerce, these provisions clarifying the reach of US antitrust law for conduct involving trade or commerce with foreign nations, regardless of where the conduct takes place: 15 U.S.C. § 6a (Sherman Act); § 45(a)(3) FTC Act. According to Section 6a of the Sherman Act, Sections 1-7 of the Act shall not apply “to conduct involving trade or commerce (other than import trade or import commerce) with foreign nations unless [...] such conduct has a direct, substantial, and reasonably foreseeable effect” “on trade or commerce which is not trade or commerce with foreign nations, or on import trade or import commerce with foreign nations”, or “on export trade or export commerce with foreign nations, of a person engaged in such trade or commerce in the United States”. This rather complex provi-

emphasis of competition law regimes around the world to sanction restrictions to innovation or potential competition, which is of particular interest for the digital economy, this standard may lead to an expansive extra-territorial application of competition law to the extent that the conduct in question may reduce innovation, potential competition and thus harm the consumers or suppliers in the specific jurisdiction. Quite often the only limiting principle for the extra-territorial enforcement of competition law may not relate to the issue of prescriptive jurisdiction, which as we mention can be broadly interpreted in these situations, but to enforcement jurisdiction, the latter issue framing also the exercise by an authority of its prescriptive jurisdiction. Indeed, it might prove impossible for a jurisdiction to apply competition law and impose remedies on an undertaking that has no presence, in terms of holding assets, in its territory. In this case, the enforcement of any remedies, in particular if these are structural, would require the close cooperation of the home jurisdiction where the undertaking is established or has its main centre of activity.

As a recent OECD report acknowledges, in a number of recent antitrust cases around the world, competition authorities took different approaches to the territorial delimitation of remedies, and interpreted in different ways comity consideration, which may lead to limit the scope of remedies¹³⁶². In the US, courts take into account different factors, in addition to effects, such as “whether the interests of, and links to, the United States – including the magnitude of the effect on American foreign commerce – are sufficiently strong, vis-à-vis those of other nations, to justify an assertion of extraterritorial authority”, an effect on US commerce on its own being insufficient to establish prescriptive jurisdiction as a matter of international comity and fairness¹³⁶³. This balancing

sion has led to various efforts of interpretation by the US courts, in particular focusing on the nature of the causal link to establish direct, substantial, and reasonably foreseeable effects. The 9th circuit had adopted a strict standard for directness of the effect on US commerce, as the effect must follow from “an immediate consequence of the defendant’s activity.” *US v LSL Biotechnologies*, 379 F.3d 672 (9th Cir. 2004). In 2012 the Seventh Circuit took a different approach in *Minn-Chem Inc. v. Agrium Inc.*, 683 F.3d 845 (7th Cir. 2012), where it introduced the “reasonably proximate causal nexus” standard, which enables a more expansive interpretation of Section 6(a) of the Foreign Trade Antitrust Improvements Act (FTAIA). This more expansive view was confirmed in the recent *Motorola II* judgment of the Seventh Circuit, *Motorola Mobility v. AU Optronics Corp.*, 773 F.3d 826 (7th Cir. 2014), petition for cert. filed, 83 U.S.L.W. 3745 (U.S. March 16, 2015), where the Seventh Circuit revisited a more restrictive interpretation of Section 6(a). In *Motorola I*, *Motorola Mobility v. AU Optronics Corp.*, 746 F.3d 842 (7th Cir. 2014), the Court rejected the existence of a “direct” effect on U.S. commerce because of the fact that the anti-competitive behaviour was affecting intermediary and not final products. The Second Circuit also adopted the more expansive “reasonably proximate causal nexus” standard in *Lotes Co. v. Hon Hai Precision Indus. Co.*, 753 F.3d 395 (2d Cir. 2014) (conduct was considered as within the scope even if it affected intermediary products). In a recent judgment the Ninth Circuit nevertheless insisted on the restrictive approach of “the immediate consequence test,” *US v. Hui Hsiung*, 778 F.3d 738 (9th Cir. 2015), petition for cert. filed, 83 U.S.L.W. 3745 (U.S. March 16, 2015) See, in the EU

1362 See, OECD, Roundtable on the Extraterritorial Reach of Competition Remedies – Issues Paper by the Secretariat, DAF/COMP/WP3(2017)4, noting at ¶ 23, ‘the imposition of different enforcement decisions and remedies against the same conduct is the natural result of competition rules, standards, and enforcement practices not being aligned across the world (in spite of an increasing convergence in competition regimes and enforcement procedures), as well as of market conditions differing from one territory to the next, thus justifying different decisions’.

1363 *Timberlane Lumber Co. v. Bank of America*, 549 F.2d 597 (9th Cir. 1976)

approach, which has been compared to a “jurisdictional rule of reason”¹³⁶⁴, enables the US courts to tame the unilateralism of the effects doctrine with regard to the extraterritorial enforcement of the Sherman Act. The jurisprudence of the EU courts has also examined the application of the extraterritoriality principle, for prescriptive jurisdiction but similar principles would also apply for remedial jurisdiction, from the perspective of the principles of non-interference and proportionality, which may come close to comity¹³⁶⁵. The principle of comity was also mentioned a few times by Advocate General Wahl in his Opinion in *Intel*¹³⁶⁶, the CJEU has not yet explicitly endorsed such an approach and it seems that the broad language used in *Intel* to determine when it is foreseeable that a conduct will have an immediate and substantial effect in the EU may render the application of such doctrine in EU competition law purely hypothetical¹³⁶⁷. For instance, in *Innolux*, neither considerations of comity, nor the risk of concurrent penalties imposed by foreign competition authorities bended the approach of the CJEU, which repeated its well-established jurisprudence that ‘neither the principle *non bis in idem* nor any other principle of law obliges the Commission to take account of proceedings and penalties to which the undertaking has been subject in non-member States’¹³⁶⁸.

Of course, beyond comity considerations and their eventual role in imposing competition law remedies extraterritorially, there might be some more practical concerns pertaining to the ability of all jurisdictions to enforce competition law remedies outside the territory of the imposing authority and to ensure compliance by a non-national in another territory. This may be problematic for smaller jurisdictions, in particular if the competition law remedies need to be imposed against undertakings that do not dispose of productive assets in the specific jurisdiction. Although the principle of proportionality usually leads to the competition law fine being limited to the turnover on the affected market, and most frequently this affected market coincides with the national borders of the jurisdiction imposing the remedy, one may not exclude the possibility, as competition law is now more frequently enforced to protect innovation and potential competition, in particular in the context of the digital economy, that a jurisdiction imposes a remedy against a digital platform that does not dispose of any assets in the specific jurisdiction and that the consumers of this jurisdiction are affected through indirect cascading effects across the digital value chain. This raises questions, first as to the prescriptive jurisdiction of the specific competition law to deal with indirect effects, and second as to the remedies that may be practically imposed.

Issues, such as this have already arisen with regard to antitrust patent remedies imposed in the context of the Qualcomm case in South Korea in 2016¹³⁶⁹. KFTC imposed

1364 The term was first coined by K. Brewster, *Antitrust and American Business Abroad* 18-21 (1958).

1367 See, Case C413/14 P, *Intel Corporation Inc v. European Commission*, para. 51 (noting ‘that it is sufficient to take account of the probable effects of conduct on competition in order for the foreseeability criterion to be satisfied’)

1368 Case 231/14 P, *InnoLux Corp. v. Commission*, ECLI:EU:C:2015:451, para. 75.

1369 For a discussion, see OECD, *Roundtable on the Extraterritorial Reach of Competition Remedies – Issues Paper* by the Secretariat, DAF/COMP/WP3(2017)4, 16.

remedies to Qualcomm for various anticompetitive practices involving refusal or restriction of licensing of mobile communications SEPs, coercion exercised against handset makers to sign unfair licence agreements, or to license their patents for free. The remedies imposed by the KFTC included a mandatory obligation for Qualcomm to propose terms for licensing its mobile SEPs, to submit to binding arbitration in all cases where agreement is not reached, the obligation to supply handset makers with modem chipsets even if the handset maker has not licensed Qualcomm's etc.. Qualcomm argued that, the remedy had extraterritorial effects as it applied to foreign territories and patents registered in a foreign country, and claimed that this would infringe these countries' sovereignty. The argument was to consider international comity, and limit the scope of the application of the order to licences in Korea and patents registered in Korea. The KFTC held instead that the conduct of Qualcomm concerned enterprises and patents across the world, it had an impact on the global market, including South Korean consumers, and that, under these circumstances, in order to guarantee the effectiveness of the remedy and to remove successfully the anti-competitive effects, the scope of the order had to extend beyond Korea and Korean patents. This was particularly important in view of the international dimension of Qualcomm's business model and the fact that transactions were so connected across territories that the effects of the illegal conduct were likewise closely connected across national borders. The KFTC applies a number of principles when designing the remedy, in particular effectiveness, proportionality, correlation, clarity and specificity, the practicality and lawfulness of the implementation of the remedy. This remedy was criticized by some authors as constituting an 'intentional overreach' of jurisdiction by the KFTC, in particular the fact that the corrective order compels Qualcomm to amend or enter into contracts outside of Korea that it otherwise would not be required to enter into, and establishes a non-appealable arbitration process on virtually all of Qualcomm's licensing negotiations, wherever they take place¹³⁷⁰. Indeed, according to this view, the remedy applies without reference to actual effects in Korea, and may be of concern for virtually every enterprise in the smartphone value chain, thus covering the entire global ecosystem of smartphone component manufacturers and handset makers.

One may avoid this problem by conducting a thorough analysis of the domestic effect of a specific conduct on home consumers, or home total welfare, before framing the geographic scope of the remedy. This could provide some assurance on the unintentional (in terms of protectionism) nature of the extraterritoriality of the remedy, avoid different types of jurisdictional conflicts, for prescriptive or enforcement jurisdiction, and would improve overall legal certainty. However, competition authorities, also in developing jurisdictions, should be able to protect their consumers and the competitive process. If these are impacted negatively, because of conduct by foreign undertakings taking place elsewhere, and produce qualified effects, then competition law remedies should be imposed. It becomes also important to acknowledge that the digital economy may require a fresh assessment of indirect effects and the definition of the required causal link in

1370 J. F. Rill & J. M. Taladay, *The KFTC's Extraterritorial Overreach*, CPI November 26, 2017, available at <https://www.competitionpolicyinternational.com/author/nancy-2/>.

order to establish jurisdiction, in particular in view of the complexity of ecosystems and the emergence of digital value chains. This is an important issue for future research.

A possible way out of this conundrum is to enhance international cooperation, also in designing appropriate remedies, in particular during today's globalized and digitalized economy. A possible first step will be the sharing of information, between like-minded authorities, or in the context of existing cooperation networks (e.g. BRICS) that could be organized by different MoUs, one dealing with merger issues and one with antitrust. Some prior informal communication and concertation may also be fruitful for developing BRICS-wide remedies that may address competition law problems that could be of concern for all or a number of BRICS jurisdictions. If one follows a maximalist scenario this could even take the form of BRICS-wide or global commitments by the digital platform to the authorities, the latter acting jointly. These processes may be combined with the sharing of analytical tools, industry intelligence and best practices in the context of a research consortium or research platform.

5.3. The interaction of competition law with other legal fields in the digital economy: a separate fields approach or a regime of mutual reinforcement?

Competition law is one among various tools for state intervention in markets, and its contours must be defined with regard to other forms of state intervention, such as regulation¹³⁷¹. Governments intervene widely in markets to achieve various policy goals. Sometimes these policy goals align with one another and sometimes they conflict and require various trade-offs in policy responses, such as to pursue efficiency, to correct market failures, or to ensure equity and distributive justice.

The broader competition policy (which includes not only competition law but also other measures to address issues of competition in the economy) interfaces with state activity across many different levels of how government organizes economic behaviour. Government organizes economic activity in part through the shape and nature of regulation and overall state involvement. Understanding the distinction between competition law and policy clarifies competition authorities' capabilities and limitations when it comes to promoting competition in situations of a broader regulatory overlay. When considering the question of institutional design, how countries design optimal competition policy involves three choices: what to leave to the jurisdiction of competition law (and competition agencies and judges), what to assign to noncompetition authorities (such as sector regulators) exclusively as part of their jurisdiction, and how to establish concurrent jurisdiction among the competition authority and two or more regulatory authorities.

Conflicts between competition law and regulation may be direct, if regulation affects the core parameters of competitive markets by restricting competition on price, entry and

¹³⁷¹ There is a massive literature on this distinction between competition and regulation, perceived as separate spheres but still in constant interaction with each other. We note some recent contributions in Europe: N Dunne, *Competition law and Economic Regulation – Making and Managing Markets* (CUP, 2015); J Drexel & F DiPorto (eds.), *Competition Law as Regulation* (Edward Elgar, 2015).

quantity, as it is often the case for economic regulation, or lateral, in case these core dimensions of competition are not directly targeted, but regulation may nevertheless indirectly affect them, as it may be the case in situations of social or technical regulation. Economic regulation denotes the government intervention in a sector to correct a market failure arising from e.g. a natural monopoly (telecom, energy), or asymmetric information. It acts *a priori*, requires continuous monitoring and is intrusive in management. In contrast, competition law consists in a set of rules for market operation that prevents and sanctions abuses of market power, across all sectors. It acts *a posteriori*, once behavior is observed and mostly relies on the dissuasive power of sanctions. From this perspective, it is a less intrusive tool for market management in comparison to regulation.

Economic regulation's role is complementary to competition law since regulation controls monopolies that would never function efficiently under competition, its main function being to adopt measures that can control monopoly pricing. By ensuring non-discriminatory access to necessary inputs, e.g. network infrastructure, economic regulation may also facilitate competition in markets, thus enabling a greater scope of intervention for competition law. The less the regulatory regime interferes with the workings of the market, the more room for competition law. Expanded confidence in competition and markets may lead some previously regulated sectors to towards a specific competition law regime, taking into account the specificities of the economic sector, and even leading to the application of general competition law rules. This movement across the regulation/competition continuum may be observed in various sectors, such as airlines, maritime transports, telecoms. However, it may also be substitutable to competition law, as experience has shown that when markets or segments of network industries become competitive then sector-specific regulation is often substituted by competition law. Indeed, this may happen when the interaction of competition law and regulation could prove problematic, in particular if the regulatory regime aims to control prices, restrict entry, give incumbents a competitive advantage, or requires or permits some practice that competition law prohibits. These risks of substantive conflict may be exacerbated if different institutions are in charge of competition law enforcement from those in charge of regulating the specific economic sector.¹³⁷²

The situation is more complex with regard to social and technical regulation, which for instance sets and monitors standards to ensure compatibility between various products, to address privacy, or safety and environmental concerns. One may distinguish between situations of lateral conflict which may occur because competition law enforcement can jeopardise the aims followed by these various regulatory tools, from what we can call situations of regulatory osmosis, that is, the absorption of regulatory aims in the enforcement of competition law. This process may occur as a result of the pressure to interpret and enforce competition law principles in congruence to the aims and the

¹³⁷² This may be the case in the EU, as the Commission and a network of National Competition Authorities (NCAs) are in charge of competition law enforcement but National Regulatory Authorities (NRAs) are in charge of regulation. In the UK, the risk of conflict is mitigated by the fact that sector-specific regulators have concurrent enforcement powers with regard to competition law enforcement in their respective economic sector of responsibility.

structure of the entire legal system to which competition law is integrated. It is we think uncontroversial to argue that a competition authority or a judge enforcing competition law should strive to interpret the law in accordance to the broader moral and legal principles undergirding its legal system.

One may distinguish two broad situations here.

First, it is possible that competition law includes among its own objectives the consideration of public policy or that sector-specific regulators that have concurrent jurisdiction to apply competition law may have more than one aims in their mission statement and they often need to take into account and satisfy all these objectives.

Second, even if one does not integrate these concerns as 'objectives' to be followed by the competition authority, one needs to 'take into account' the broader principles of the legal system when interpreting the law, focusing on the way these are transcribed in its legal and institutional context, in particular for areas like competition law, where the legal rules do not provide much detail on the way one should interpret them, and statutory interpretation plays an important role. Hence, one may distinguish between various degrees of the 'duty' to take into account public interest concerns followed by social and technical regulation. A strong and extensive in scope duty if these are listed among the objectives of competition law or in the mission statement of regulators enforcing competition law, which means that the decision-maker should maximise all the objectives or to the extent there is some hierarchy between them prioritise some objectives. A weaker one, in all other circumstances, when these objectives must be taken to a certain degree into account so that the legal system does not create conflicting demands from economic actors, and, more broadly, the integrity of the legal system does not suffer.

The implementation of these broad principles in the digital economy will require a joint effort from competition authorities, horizontal and sector-specific regulators, as well as courts. The Facebook case in Germany provides an interesting illustration of the difficulties that may lie ahead when competition authorities rely on other areas of law, in the specific occurrence data protection law, to put forward theories of harm that almost automatically conclude that there is a competition law infringement from the moment a specific conduct adopted by a dominant undertaking infringed data protection law, or any other area of law, the authority balancing simultaneously interests under antitrust law *and* data protection law¹³⁷³. This approach was rejected by a decision of the OLG Düsseldorf of 26 August 2019¹³⁷⁴, the Court taking a different perspective on the question of whether an abuse of market power by Facebook can be based solely on the assumption of the Bundeskartellamt that the conditions of use at issue violate mandatory provisions of data protection law. The Bundeskartellamt assumed that the infringements of data protection law it had identified was only made possible by Facebook's position of market power (causal link). As a result, users would have virtually no option

1373 Bundeskartellamt, Facebook decision (2019), paras. 894-913, available at https://www.bundeskartellamt.de/Shared-Docs/Entscheidung/EN/Entscheidungen/Missbrauchsaufsicht/2019/B6-22-16.pdf?_blob=publicationFile&v=5,

1374 http://www.olg-duesseldorf.nrw.de/behoerde/presse/Presse_aktuell/20190826_PM_Facebook/20190826-Beschluss-VI-Kart-1-19-V_.pdf

but to agree to the terms of the contract, which constitutes abusive behaviour. The OLG Düsseldorf, however, rejected this assumption on the grounds that an (assumed) violation of data protection law by a dominant company does not necessarily constitute an abuse of market power. The court stated, that the Bundeskartellamt had not sufficiently elaborated why it was Facebooks market power that enabled them to enforce the terms and conditions upon the users. Failing to do so, it was not comprehensible why a contractual partner affected by a data protection law infringement of a dominant company was worthy of protection by competition law while the contractual partner of a non-dominant firm in the same position was not. This puts emphasis on the need for an independent competition law assessment, in addition to a data protection law one, *before* concluding as to the existence of an abuse. The court furthermore pointed out that the data provided by the user to Facebook can be endlessly duplicated, which is why the user is not economically weakened by the processing of data. The creative interaction between competition law and other regulatory regimes on data protection, interoperability, data portability, at the level of building specific theories of harm for the digital economy opens an important space for experimentation for competition authorities in the future.

5.4. Re-designing competition law remedies and procedures for the digital economy

These changes may take two forms: (i) ensure the rapidity of competition law enforcement so as to avoid acting in situations when market tipping has already occurred and it might prove impossible to reverse the anticompetitive outcome; (ii) develop remedial action that takes into account the broad effects of the anticompetitive conduct, which might better reflect the complexity of digital markets.

5.4.1. Rapidity of enforcement action: interim measures in order to ensure the effectiveness of enforcement in the digital era

Striving to catch up with the fast-passed digital world, some competition authorities are considering utilizing interim measures to contain the possible threat to competition pending the final conclusion of a long and complicated investigation. A recent announcement by the European Commission in the Broadcom investigation started the debate about the use of said measure as temporary remedy in the rapidly evolving digital economy.¹³⁷⁵ Another tool has also been used frequently by competition authorities in recent years in order to close competition investigations in exchange for commitments put forward by relevant parties i.e. commitments or consent orders.

In this Section we will discuss the use of such measures from a global perspective, main-

¹³⁷⁵ The European Commission Press release, Antitrust: Commission opens investigation into Broadcom and sends Statement of Objections seeking to impose interim measures in TV and modem chipsets markets Brussels, 26 June 2019. Available at https://europa.eu/rapid/press-release_IP-19-3410_en.htm (last accessed August 25, 2019)

ly focusing on the EU (including the UK) and the US as well as from a BRICS perspective, with a focus on digital market cases. In each Section, we will answer the following questions: are interim measures / injunctions and commitments among the enforcement tools in the jurisdiction? If yes, what are the relevant criteria to order said measures? How have these orders been reviewed by the courts? Finally we will compare the use of interim measures with commitment decisions.

5.4.1.1. Interim Measures and Commitment Decisions in EU Competition Law and Practice

5.4.1.1.1. Interim measures

The right to adopt interim measures is stipulated under Regulation 1/2003.¹³⁷⁶ The regulation and practice set the criteria for adopting said measures. To grant an interim relief, the measure must address a conduct of an undertaking that gives rise to a *prima facie* finding of infringement of EU competition law, and only used in cases urgency to address risk of serious and irreparable damage to competition, or, a situation which is intolerable for the public interest.¹³⁷⁷ The measure should also be indispensable to the effective resolution of the case. It should be temporary and conservatory addressing a time-sensitive situation until a final decision is adopted. It basically should aim to retain the *status quo* pending a final decision. The EU Commission should also take into consideration the legitimate interest of all parties involved. In addition, the EU Commission is bound by the principles of procedural fairness¹³⁷⁸ and availability of judicial review of these measures.¹³⁷⁹ Under the regulation, the EU Commission can order interim mea-

1376 Article 8 of Regulation 1/2003 Available here <https://eur-lex.europa.eu/LexUriServ/LexUriServ.do?uri=OJ:L:2003:001:0001:0025:EN:PDF>

1377 "The 'public interest' is a reference to EU competition policy objectives as well as the interests of Member States." Alec J. Burnside and Adam Kidane, Interim Measures: An overview of EU and national case law, *Concurrences*, N°86718, June 7, 2018, p.11.

1378 General procedural safeguards apply (Regulation 17 and Regulation 99/63). These rights include the obligation to issue statement of objection, access to file and opportunity to comment (in writing or oral hearing hearing).

1379 Initially, there was no express authority granted to the European Commission to adopt interim measures under EU competition rules. Rather the use of interim measures were introduced to EU competition enforcement via court order in Camera Care case. In this case, the Court confirmed that the Commission enjoys the power to order interim measures and provided guidelines for the Commission to follow to grant these provisional measures Camera Care Ltd. v. Commission (No. 792/79), [1980] 1 E.C.R. 119, 127. In this case the plaintiff, Camera Care Ltd, alleged that Hasselblad (GB) Ltd. and Victor Hasselblad A/B of Sweden have refused to supply Camera Care with Hasselblad cameras and spare parts in violation of competition rules and requested the commission take an interim measure in this regard. The Commission refused on the basis that it lacks the power to adopt interim measures. Camera Care then challenged the decision in court and won. In its decision the court found that "within the bounds of its supervisory task conferred upon it in competition matters by the Treaty and Regulation No 17, to take protective measures to the extent to which they might appear indispensable in order to avoid the exercise of the power to make decisions given by Article 3 from becoming ineffectual or even illusory because of the action of certain undertakings." Other relevant cases include ECS/AKZO (interim measures), 26 O.J. EUR. COMM. (No. 252) 13 (1983), [1983] ECS claimed that AKZO's price cutting caused ECS to lose a substantial part of its business and forced ECS to match AKZO's prices, creating a real risk that ECS would have to cease trading altogether.³⁰ The Commission granted interim measures, ordering AKZO not to sell below certain prices

sure (*ex officio*) to address damage to competition but not to individual undertakings. However, a concerned party may make its request to the NCAs. Despite the express provision under Regulation 1/2003 of the right of the Commission to adopt interim measures, it was hardly used.¹³⁸⁰ Among the reasons discussed for this limited adoption of interim measures are (i) the limited resources versus increased burden on the Commission that opens the on-going investigation to judicial review and further litigation and (ii) the high evidentiary burden in order to satisfy the substantive test for issuing interim measures. Most relevant here is the difficulty in adopting interim measures in complex or novel cases involving conduct that do not give rise to clear-cut infringements to EU competition rules.

However, the EU Commission is studying the matter taking into consideration the practice of other NCAs, especially France, in this regard.¹³⁸¹ In its recent Directive (EU) 2019/1, the EU Commission stated that NCAs should have the power to impose interim measures, as a minimum, in cases where an NCA has made a *prima facie* finding of infringement of Article 101 or 102 TFEU and where there is a risk of serious and irreparable harm to competition.¹³⁸² It is added that the EU Commission will encourage the use of interim measures in order 'to deal with developments in fast-moving markets'.¹³⁸³

Box 6.1.: NCAs across the Channels

Lowering the burden of proof for interim relief French Google Cases

The French competition law confers to the French Competition Authority ("FCA") power to order interim measures (injunction) backed up by a coercive fine against the infringing party. The FCA can adopt interim measures on the ground that the potentially infringing conduct results in 'a serious and immediate prejudice to the economy in general, to the sector at stake, to the interests of consumers or to those of the complainant'.

until the final decision was reached. C.M.L.R. 694.6. Ford-Werke AG (interim measures), 25 O.J. EUR. COMM. (No. 256) 20 (1982), [1982] 3 C.M.L.R. 2677. Ford of Europe Inc. and Ford Werke AG v. Commission (Nos. 228/82 & 229/82), [1984] 1 C.M.L.R. 649.8. Ford case, where German dealers were complaining about protection against parallel imports extended to UK dealers. The Commission adopted an interim measure ordering Ford Germany to withdraw the circular adopted to that effect and have right-hand drive cars be part of their delivery range for German dealers. For a detailed account see Virginia Morris, Interim Measures in EEC Competition Cases, 3 Int'l Tax & Bus. Law. 102 (1985).

1380 Research found that before Regulation 1/2003 came into force, interim measures were rarely used where in only 8 out of 13 cases the Commission has considered interim measures. There has only been one case – in over 20 years between Camera Care and the entry into force of Regulation 1/2003 – where an interim measures decision was adopted *ex officio*, namely Ford Werke. Following the entry into force of Regulation 1/2003, except for an attempt in 2001 in IMS case, there have been no interim measures decisions. In the IMS case the Commission subsequently withdrew the decision to adopt interim measures following the EU court judgment resulting in the suspension of the interim measures. See Burnside and Kidane, *supra* n. 4 at 8 and Case COMP D3/38.044 NDC Health/IMS Health: Interim Measures, OJ 2002 L59/18.

1382 Article 11 of the Directive (EU) 2019/1 of the European Parliament and of the Council of 11 December 2018 to empower the competition authorities of the Member States to be more effective enforcers and to ensure the proper functioning of the internal market PE/42/2018/REV/1, OJ L 11, 14.1.2019, p. 3 th.

1383 Ibid.

The experience of the FCA has successfully applied interim measures in cases involving energy markets, broadcasting and fast-moving markets (like online advertising). Thus, in 2010 FCA imposed interim measures on Google following a complaint from Navx alleging an abuse of dominance after its AdWords contract was terminated (Navx decision 10-MC-01). The very recent case also involves Google that suspended the Ad service accounts of Amadeus, the complainant, without explanations. In this case FCA justified the interim measures because Amadeus had suffered a massive and very sudden loss of turnover (drop of 90% between 2017 and 2018) and was under the threat of exiting the market. The interim measures imposed included:

- clarification of the Google Ads rules applied to directory enquiry information services;
- a review of Amadeus' situation under these new rules with a view to giving it access, as appropriate, to the Google Ads service again if the ads comply with them.

UK Online Auction Platform Market

In 2014, the CMA was given enhanced powers to impose interim measures but to date, it has not yet used them. In contrast to the EU Commission where it must show (i) a 'serious and irreparable harm', (ii) assess the irreparable damage to competition (not a single competitor) and (iii) be able to demonstrate a prima facie infringement case, the CMA should only have a reasonable suspicion of an infringement. The Auction Services case is to date the CMA's only abuse of dominance case in digital markets, and the only case in which the CMA has considered interim measures.

Following the opening of an investigation by the CMA into ATG Media, Bidon. This, a competitor to ATG Media, made an application for interim measures, which ultimately resulted in ATG Media offering commitments to address the competition concerns that had been identified by the CMA. As a result, the CMA's 2018/2019 annual report expressly identified interim measures as a tool they will be using more, referring to the online auction platform case as an example. However, the UK competition authority remains cautious about accepting applications and the costs of an application can affect the approach of both an applicant and a company subject to a complaint.

At the moment, there has been no divergence in approach or outcomes and this may reflect the CMA's (understandable) hesitancy to practically implement the legal changes or complainants not yet fully taking advantage of the opportunity of the law.

5.4.1.1.2. Consent orders (commitment decisions)

In contrast to interim measures, consent orders (commitments) are used more frequently by the European Commission to conclude cases. Under Article 9 of Regulation (EC) No 1/2003, an undertaking may offer a commitment to address competition concerns raised by the EU Commission.¹³⁸⁴ The EU Commission may accordingly conclude cases by a commitment decision without the establishment of an infringement. Com-

¹³⁸⁴ Regulation (EC) No 1/2003. Available at <https://eur-lex.europa.eu/legal-content/EN/TXT/PDF/?uri=CELEX:32003R0001&from=EN> (last accessed August 28, 2019).

mitments may not include the imposition of a fine and thus are not used in cases with the most serious violations such as cartels. Commitments may be behavioral (provide certain services or goods under specified conditions) or structural (divestiture of assets of the concerned companies).¹³⁸⁵ The European Commission may decide to adopt a decision making the commitment binding on the parties. The same procedural rights of the parties under competition proceedings are also extended in a commitment procedure. While third parties can submit comments pursuant to a Notice of Commitment published by the Commission.

From 2004 to 2016, in 35 out of 57 antitrust decisions (excluding cartels), the Commission adopted commitment decisions with the majority being behavioural commitments and about a quarter were structural.¹³⁸⁶ These were used, in particular, in markets being subject to liberalisation, such as the energy sector and markets that require prompt intervention. They are also subject to judicial review.

5.4.1.2. Interim measures and Negotiated Settlement (Commitment) in US Antitrust Law and Practice

5.4.1.2.1. Interim measures

In U.S. antitrust law, two concepts applied by the courts and used in merger cases have the same effect as interim measures or relief, namely temporary restraining orders (TROs) and preliminary injunctions. While both the government and private parties can seek interim measures in civil cases.¹³⁸⁷ TROs require proof of immediate and irreparable injury that will occur before the adverse party has a chance to oppose the motion and typically last less than 10 days.¹³⁸⁸

Courts however demand more demonstrative and exact proof for preliminary injunctions. The criteria for such injunction are: (1) a substantial likelihood of success on the merits; (2) a substantial likelihood that failure to grant relief will cause irreparable injury for which monetary damages cannot substitute; (3) the potential damage outweighs any harm that the injunction may cause to the opposing party; and (4) the injunction will promote the public interest.¹³⁸⁹ When the government requests this relief, a court may presume it has satisfied the fourth element. Preliminary injunctions can take the form of a negative or positive requirement. They can take the form of a negative injunction

1385 OECD, EU Submission, Commitment Decisions In Antitrust Cases, DAF/COMP/WD(2016)60, June 2016, p. 8. [https://one.oecd.org/document/DAF/COMP/WD\(2016\)60/en/pdf](https://one.oecd.org/document/DAF/COMP/WD(2016)60/en/pdf) (last accessed August 28, 2019).

1386 "16 decisions involved Article 101 TFEU prohibiting anticompetitive agreements, 18 decisions involved Article 102 TFEU prohibiting abuse of dominance, and one involved both Articles. 74% of all commitments was of behavioural nature and 26% was structural." *ibid*, p. 8. 1389 *Id.*, 542.

(orders a party to cease particular behaviour) or a positive injunctions (demand an affirmative set of actions: for example, licensing technology, continuing supply, or granting access to indispensable inputs).¹³⁹⁰ To decide the merits of a preliminary injunction, courts balance the probability that the agencies ultimately will succeed on the merits against the public (not private) equities.¹³⁹¹ In this context, courts may consider the efficiencies that defendants proffer.

In all of the cases pertaining to preliminary injunctions or TROs available,¹³⁹² relevant cases involved mergers rather than unilateral or coordinated conduct. In this regard, the antitrust agencies seek to prevent parties from completing a merger,¹³⁹³ filing for interim measures to maintain the status quo while administrative or court proceedings go forward. They usually argue that a completed merger will prevent direct competition between the parties, precluding lower prices and better services and in this case an interim measures will enable the Court to order effective relief after deciding the merits of the merger.¹³⁹⁴ The agencies may claim that they cannot re-establish effective competition after the merger, or that substantial harm to competition will occur in the interim. *Id.*, Para. 80. Courts will consider whether entry or expansion could counteract anticompetitive effects in the near term.

Box 5.2: Preliminary injunctions in US antitrust enforcement (select cases in digital markets)

In CCC Holdings, a technology merger the FTC sought a TRO and a preliminary injunction to prevent the merger from causing higher prices, worse product quality, and fewer services. Nearly immediately after the District Court issued a TRO and preliminary injunction, the parties abandoned the merger. This result customarily occurs in these cases.

In U.S.A. v. Microsecond Corp, the DOJ has requested a TRO and a preliminary injunction to prevent the acquiring party in a merger from destroying, selling, or ceasing the operations of the target's assets.

In FTC v. Warner Chilcott Holdings Co., LTD, a permanent injunction case presented facts in a non-merger context that a court may consider as close to sufficient to warrant interim measures. It involved a horizontal agreement not to compete between a branded and generic seller of prescription drugs.

The generic producer planned to sell the drug upon receiving FDA approval. The branded drug maker agreed to pay the generic producer \$20 million if it refrained from selling the drug in the U.S. for 5 years. *Id.*, Para. 3.

¹³⁹⁰ *Id.*, 543.

¹³⁹¹ *Id.*, Para. 78.

¹³⁹² Author's review of available cases at the FTC and DOJ websites (as of August 2019).

¹³⁹³ The FTC has authority to pursue provisional relief under Sect. 13(b) of the FTC Act, 15 U.S.C. Sect. 53(b), and both agencies have that authority under Sect. 16 of the Clayton Act, 15 U.S.C. Sect. 26. *FTC v. Staples*, Complaint for Temporary Restraining Order and Preliminary Injunction Pursuant to Sect. 13(b) of the FTC Act, Civil Action No. 15-cv-02115, p. 2 (D.D.C. 9 Dec. 2015).

¹³⁹⁴ *Id.*, Para. 21

The effect of the agreement was to deprive consumers of a cheaper option to an expensive drug. *Id.*, Para. 4. In this context, a court might grant a preliminary injunction when the FDA was about to approve the drug, or to keep the generic maker from ceasing to sell the drug.

5.4.1.2.2. Negotiated settlements (commitments)

As for commitments, both agencies, the DOJ and the FTC, use this tool in most of their mergers as well as civil non-merger antitrust cases.¹³⁹⁵ The test for an acceptable negotiated settlement (commitment) is whether it addresses the anticompetitive conduct in a way that eliminates the harm and prevents its recurrence.¹³⁹⁶

Figure 5.4.: Agencies settlements 2011 -2016

1395 'DOJ files consent decrees, or civil consent judgments, in a U.S. federal district (trial) court to obtain effective relief without taking a case to trial. The FTC issues negotiated administrative consent orders under its statutory authority, to resolve violations without the need for a trial. DOJ and FTC use consent decrees and consent orders, respectively, most often to settle merger cases, but also use them to settle alleged competition violations that include both unilateral conduct, such as exclusive dealing and monopolization,⁴ and concerted action cases, such as unlawful agreements'. OECD, US Submission, Commitment Decisions In Antitrust Cases, DAF/COMP/WD(2016)60, June 2016, Available at [http://www.oecd.org/officialdocuments/publicdisplaydocumentpdf/?cote=DAF/COMP/WD\(2016\)23&doclanguage=en](http://www.oecd.org/officialdocuments/publicdisplaydocumentpdf/?cote=DAF/COMP/WD(2016)23&doclanguage=en) (last accessed August 28, 2019).

1396 'While considering a consent decree, the court shall determine whether the consent decree is in 'public interest'. (a) the competitive impact, including termination of alleged violations, provisions for enforcement and modification, duration or relief sought, anticipated effects of alternative remedies actually considered, and any other considerations bearing upon the adequacy of such judgment; and (b) the impact of entry of such judgment upon the public generally and individuals alleging specific injury from the violations set forth in the complaint including consideration of the public benefit, if any, to be derived from a determination of the issues at trial.' Ibid OECD

5.4.1.3. Interim Measures and Commitment Decisions in BRICS Countries Competition Law and Practice

5.4.1.3.1. Interim measures

The availability of interim measures or injunctions to competition authorities varies greatly among BRICS countries.

In **Brazil**, CADE has powers to issue interim measures in conduct cases.¹³⁹⁷ Specifically, the General Superintendence or the Reporting Commissioner can adopt interim injunctions in any phase of the proceedings when there are “sound reasons to believe that the defendant directly or indirectly caused or may cause irreparable or substantial damages to the market, or that he/it may render the final outcome of the proceedings ineffective”.¹³⁹⁸ The measures entail the immediate cessation of the practice and, if materially possible, the reversal to the situation before the practice.¹³⁹⁹ The authorities can impose daily fines of 5,000 BRL, which can be increased up to 50 times, depending on the gravity of the conduct and the economic situation of the parties.¹⁴⁰⁰ At the request of the affected party, these measures can be reviewed by CADE’s Administrative Tribunal.¹⁴⁰¹

CADE has applied interim measures in some cases during the past years, including: a) in 2009 the payment card vertical conduct case, in which interim measures have been adopted and upheld against ‘major players with presence in Brazil to refrain them to maintain the exclusivity provisions provided in their agreements’;¹⁴⁰² b) in 2015, in the gas supply unilateral conduct case, in which preventive measures were imposed against Petrobras to avoid cross subsidising its downstream consortium;¹⁴⁰³ in this case, the Superior Court of Justice upheld the decision taken by CADE;¹⁴⁰⁴ c) in 2017, in the fuel resale cartel case.¹⁴⁰⁵ d) in 2019, in the national market of services for electronic identification

of vehicles in parking spaces to ensure the sharing of infrastructure of antennas with competitors in a non-discriminatory way, summarised below:¹⁴⁰⁶

Box 5.3. – CADE's Interim Measures in the Digital Sector (2019)

After Veloe's complaint against companies CGMP and ConectCar, CADE initiated an administrative inquiry to investigate alleged market foreclosure and discriminatory practices, in the market of electronic payment solutions for parking, through digital automobile recognition technology. Veloe complained against CGMP's conditions for sharing antenna recognition and CGMP's exclusivity arrangements with the biggest parking lot company – Estapar. After Veloe's appeal to the General Superintendence's Decision to deny the request, CADE's Commissioners granted the request for provisional measures, imposing sharing obligations toward CGMP and ConectCar, which, later on, managed to reverse the remedies. The measures imposed on CGMP are still holding and they seek to avoid market foreclosure, raise of barriers to entry and discriminatory conditions in sharing parking antennas.

Source: Clarificatory Proceedings in the Appeal to Preventive Measures nº 08700.000989/2019-94 Reporting Commissioner Polyanna Vilanova. Decision 11 June 2019

The Russian competition law does not set forth any interim measures available for the competition authority.¹⁴⁰⁷ In this context, all measures imposed by the Russian FAS are based on final decisions concerned antitrust violations. FAS can issue a warning, which is enacted before the violation is formally established and aims at prevention of further harm to competition and/or consumers. However, warnings cannot be considered as interim measures, because if the undertaking complies with the warning, the competition authority does not launch the formal antitrust investigation.¹⁴⁰⁸ FAS can also ask for injunctive relief during administrative procedures in commercial courts.¹⁴⁰⁹ Such interim measures may be undertaken by a court if failure to take these measures may obstruct or render impossible the execution of a judicial act, as well as to prevent significant damage to an applicant. No statistics can be found on how often the courts apply interim measures in antitrust cases (including the cases related to digital markets), though there are certainly such examples.¹⁴¹⁰

In **India**, the Competition Commission of India ('CCI') has 'power to issue interim orders', when it is satisfied that an act in contravention of provisions related with 'anti-competitive agreements' (S.3(1)), 'abuse of dominance' (S.4(1)) and 'combinations' (S.6) has been committed and continues to be committed or is about to be committed.¹⁴¹¹ In

1410 See, for instance, injunction relief applied following the action brought by FAS of Russia against shareholders of Vimpelcom (mobile operator): Igor Tsukanov, 'Vimpelcom Appealed Against Interim Measures Imposed Following The Suit Filed By FAS' (Vedomosti, 09 June 2012) https://www.vedomosti.ru/technology/articles/2012/06/09/kontrmery_vympelkoma.

1411 Section 33 of the Competition Act, 2002, https://www.cci.gov.in/sites/default/files/cci_pdf/competitionact2012.pdf.

such situations, CCI can make orders to temporary restrain any party from carrying on such act until the conclusion of inquiry or until further orders. Thus the scope of this power seems very wide. This power, however, has not been exercised frequently by the CCI. There are at least three cases where interim relief have been allowed by the CCI,¹⁴¹² while in at least two cases interim relief sought has have been denied, which include a case related with tech firm in form of a taxi aggregator. In the latter case involving predatory pricing,¹⁴¹³ the CCI (the order dated 3 Sept 2015) denied interim relief to the applicant (a radio taxi operator) on the ground that the applicants did not prove that the loss, which has occurred or would occur, would be irreparable and that the balance of convenience was in their favor.

Article 49C of the **South African Competition Act** sets forth that a complainant can apply to the Competition Tribunal for an interim order (relief) in respect of the alleged prohibited practice. Thus, the powers to impose interim measures are reserved to the specialized court, not to the Competition Commission. Notably, the Competition Commission does not have a right to initiate interim order procedures, which is reserved exclusively to the complainant.¹⁴¹⁴ The remedy of interim relief is only available in instances of practices prohibited under Chapter 2, like price fixing, implying that the remedy is not available in merger proceedings. Section 49C of the Competition Act gives the Competition Tribunal authority to grant an interim order to a complainant, if the requirements of section 49C(2) are met, pending the final determination of the applicant's complaint filed with the Competition Commission (but no longer than 12 month in total).

The Competition Tribunal has dismissed many interim relief applications. Among the cases where the interim relief has been granted is *Directory Solutions v Trudon* (2010).¹⁴¹⁵ In this case, the Competition Tribunal applied balancing exercise and granted interim relief based on the fact that the continuous antitrust violation can harm not only to complainant, but also third parties (the complainant's customers) and that if the relief is granted, the defendant (Trudon) will suffer no business disruption.¹⁴¹⁶

In **China**, there are no interim measures provided by law to Chinese regulators in conducting investigation procedures. In private litigations, plaintiffs are entitled to seek injunction reliefs or TROs under general civil procedure law provided the urgency and necessity were proved before a court. However, there is no such precedents in competition cases.

In all the above jurisdictions, where the interim measures are allowed for competition authorities or courts, their scope seems quite broad, as they primarily seek to 'neutral-

ize' the anticompetitive conduct and prevent significant or irreparable damage to the applicant. Such measures might include: banning the undertaking involved from committing specific actions that restrict or distort competition;¹⁴¹⁷ performing the positive actions;¹⁴¹⁸ even appointing an independent administrator to run the business of an undertaking involved in a cartel (in the Brazil fuel cartel case an 'interim administrator' has been appointed to manage the gas stations owned by cartelists and set their prices without co-ordinating with other competitors).¹⁴¹⁹

5.4.1.3.2. Commitments Decisions

Commitment decisions are broadly applied by **Brazil** CADE in conduct cases ('cease-and-desist commitment')¹⁴²⁰ and within merger control (Merger Control Agreements or ACC).¹⁴²¹ They involve structural or behavioural commitments and, in practice, are usually negotiated between the parties and the Competition Tribunal rather than unilaterally imposed by the latter.¹⁴²² One of the examples of merger commitments with digital aspect is the merger between Itaú Unibanco and Mastercard (in the form of joint venture) for the creation of a new debit and credit card flag which aimed, *inter alia*, at introducing new technologies in the payment market.¹⁴²³ The commitments agreed involved creation of the new brand for the payment card, reduced duration of JV and creation of corporate governance rules.

The tool of commitment decisions does not formally exist **in Russia**.¹⁴²⁴ However, undertakings can settle their disputes with FAS during the court procedures according to Chapter 15 of the Arbitration Procedure Code of the Russian Federation. These settlement agreements often contain provisions on certain commitments of economic entities, for example, to inform FAS Russia on price changes, to ensure non-discriminatory conditions in contracts, etc.¹⁴²⁵ With regard to digital cases, the only example that could be considered as a commitment decision in the context of merger control is the pre-

1417 See *M/s Nuziveedu Seeds Limited et al vs. Mahyco Monsanto Biotech (India) Limited (MMBL) et al* (Case No. 107/ 2015): prohibition to enforce the post termination obligations that require Informants to destroy the seeds, parent-lines and germplasm, which are modified to contain the technology of the Opposite Parties.

1418 See Case No. 77/IR/Nov09 *Directory Solutions v Trudon*, South Africa (2010) where the tribunal obliged the defendant to accept from complainant without a requirement for the upfront payment certain entries to the telephone directories owned by the defendant.

liminary decision of FAS of Russia on Bayer/Monsanto deal (dated November 8, 2017), prescribing to the parties to conclude the agreement with the Center for Transfer of Technologies in order to receive the approval of the deal by FAS Russia.

Section 49D(1) of the **South African** Competition Act provides that, if the Competition Commission and a respondent “agree on the terms of an appropriate order,” the Competition Tribunal may confirm the agreement as a consent order. Unlike interim relief, a consent order is generally issued after the Commission has completed an investigation, as it has to address adequately the anticompetitive conduct and be ‘as close as possible to that it would have achieved upon a successful prosecution of the matter in the [Competition] Tribunal’.¹⁴²⁶ The statistics shows that most cases are resolved by Commission through consent orders,¹⁴²⁷ which makes it far more popular measure than interim relief. Some notable examples of consent orders include Telkom consent order (internet services),¹⁴²⁸ Pioneer Foods consent order (bread),¹⁴²⁹ Sasol divestiture consent order (fertilizers).¹⁴³⁰

In **China** commitments are used in both conduct violations (for example, in cartel cases in exchange of leniency) or within the merger control. Authorities also sometimes request for upfront buyer or fix it first remedies to cure competition concerns before issuing clearances. On 04 December 2014 MOFCOM (currently the State Administration for Market Regulation) issued the Interim Regulations on Imposing Restrictive Conditions on Concentrations of Undertakings (Remedies Regulations) that set out the process for negotiation and determination of remedies.¹⁴³¹ Some example of cases include LCD Panel cartel case (behavioural commitment),¹⁴³² InterDigital abuse of dominance case (behavioural commitments with respect to the licensing of the patent portfolio),¹⁴³³ and Rockwell Collins/UTC merger (both structural and conduct commitments).¹⁴³⁴

Our understanding is that in **India**, commitment decisions are not provided for under the competition regime.

Conclusions: Competition authorities around the world are considering updating their tool boxes for instruments to deal with the rapid, dynamic nature of digital markets. Interim measures are being considered for playing a more important role to limit the harm to competition until competition authorities can conclude their lengthy investiga-

tions in these complex markets. Although interim measures are available in all jurisdictions reviewed, their use and application are rare. This may be due to, among other things, the high evidentiary burden that needs to be met for an interim measure to succeed where the competition authority has to prove at least *prima facie* an antitrust violation and substantial/irreversible damages. In instances where the threshold is lower, France is a case in point, interim measures are being used more frequently nevertheless without jeopardizing procedural fairness requirements (see Annex 4 on interim measures in selected jurisdictions).

Commitment decisions seem far more popular tools among competition authorities. This may be due to the willingness of undertakings to enter into commitment agreements with NCAs in exchange for exculpation from antitrust violation or merger clearance. Nonetheless, expanding the use of this tool has its own set of problems such as its impact on deterrence, the risk of increasing the monitoring duties for NCAs and the risk of hindering the development of legal precedent, which is a very relevant risk for young competition regimes and in particular for new issues arising out of the digital revolution, for which there is need for guidance.

Competition authorities should consider utilizing interim measures and commitment decisions in the digital economy, both instruments playing a complementary role. Interim measures may be used within a revised framework with lower thresholds but this should only be reserved for complicated and lengthy investigations where there is risk of irreversible harm to competition (markets may tip), and this should apply to the most harmful violations, such as cartels and abuse of dominance. Commitment decisions may be utilized to address less serious violations where it is also beneficial to the competition authority to reach a swift resolution, which would save it time and resources for more serious issues and will avoid market tipping. In any case, the practice of the authority should be clarified in secondary instruments such as guidelines for predictability and transparency purposes.

5.4.2. Towards a different model of competition law remedies

5.4.2.1. Competition law remedies for a complex economy

The concept of ‘effective’ remedies does not entail the power to impose *any* remedy¹⁴³⁵. It is closely interrelated to the question of the remedial discretion of competition authorities and the judiciary in competition law cases. It is generally argued that competition law remedies are adopted with the principal aim to restore competition in the market. This objective may be conceived broadly as including first the ‘micro’ goals of putting the infringement to an end, curing the particular problem as to competition, but

1435 For a detailed discussion see, I. Lianos, Effective Competition Law Remedies. In Ph. Lowe, G. Monti, M. Marquis (Eds.), *European Competition Law Annual 2013* (Hart Publishing, 2016), 105 ; I. Lianos, Competition law remedies in Europe: Which Limits for Remedial Discretion?. In I. Lianos, & D. Geradin (Eds.), *Handbook in EU Competition Law: Enforcement and Procedure* (Edward Elgar, 2013), 362.

also the ‘macro’ goal of putting incentives in place, so as to minimize the recurrence of just such anti-competitive conduct (preventive remedies or remedies aiming at deterrence). Competition law remedies may therefore have a prophylactic (preventive) aim. They seek to ensure that there remain no practices likely to result in distortions of competition and infringements in the future. This is particularly important in the context of the fast moving digital economy where enforcement activity focuses on the possible/likely effects of the anticompetitive conduct on the future market structure, innovation and therefore future consumer harm.

In the traditional private law adjudication process, rights (or wrongs) are linked definitionally and logically to remedies. One of the principal functions of remedies is to replicate the content of the pre-existing right that has been violated. This also applies to transformative remedies (remedies transforming the right that has been violated), which also require some form of functional linkage between remedies and rights, the latter one being an implication of the principles of corrective justice and correlativity in private law adjudication. In contrast, public law process-based approaches, such as structural reform theories, challenge the fit between right (or wrong) and remedy. In this context, the linkage between remedies and rights (or wrongs) is instrumental, as the liability stage indirectly constraints the targets of the remedial process, whose aim is to provide a solution to a specifically determined (at the liability stage) *problem*. The normative parameters that have been set at the liability stage *in the form of problems* that the remedy must address operate at the same time as a guide and as a constraint to the exercise of remedial discretion in a public law context. Hence, the remedial discretion of the decision-maker, from a public law perspective, will very much depend on the way the competition law problem is initially framed. For instance, if the competition law problem is defined as market tipping resulting from the bundling practices of a dominant undertaking, this may offer a significant discretion to the competition authority to act so as to reverse the situation of market tipping, eventually by ordering the divestiture of assets (e.g. data, algorithms, human resources, IP rights) that may have significantly contributed to the outcome of market tipping. This of course raises difficult questions as to how much of this market tipping results directly from the conduct that has been found to constitute a restriction of competition, and how to deal with situations in which the market tipping may have indirectly resulted from the specific conduct, for instance in situations in which the conduct contributed to the triggering of a process that led to market tipping.

Remedies may also have a pure prophylactic function to the extent that they affect the ability (and not the incentive) of the infringers to commit equivalent anti-competitive practices in the future by focusing on specific *facilitators* of potential infringements. These may not be illegal practices in themselves, but in the specific circumstances of the case, they may facilitate illegal conduct. By including in the remedial package the prohibition of these practices, the decision-maker’s objective is not to deter the potential infringers from adopting such conduct, as this is not illegal, but to reduce their ability to commit the illegal practices.

Decision-makers dispose of various trade-off devices in order to perform this search for appropriate – to the specific circumstances – remedies. One may adopt a simple means-end rationality test, which will consider if the remedial means chosen would indeed be a rational means to a purported remedial end. This may amount to a simple suitability test, which would provide the decision-maker with a lot of discretion in adopting a remedial package, but with the limitation that the remedies should be linked rationally with some limited remedial ends. Another possibility would be to assess the proportionality of the remedial action. This trade-off device would inquire whether the means are proportionate to the remedial ends. This exercise will involve in addition to considering if the means chosen are indeed a rational means to a purported end (step 1 of the test), some assessment of the possible excessive costs of the remedial action in relation to its benefits (step 2) and whether the means chosen are the least restrictive to the affected interests' alternative (step 3). The last operation inquires whether there is a less restrictive (to the affected interests) reasonably available alternative to accomplish the same remedial end. Finally, we can regroup under the broad category of cost-benefit analysis a balancing test that attempts to measure the costs and benefits of a remedial option or of alternative remedial options, before choosing the most appropriate one. Here there is less discretion.

In view of the influence of economics in competition law enforcement, the definition of what is 'optimal' or 'appropriate' may be influenced by the view economists have on optimal deterrence (the optimal deterrence model) and on how the market equilibrium existing prior to the competition wrong may be improved by subsequent remedial action. The remedy may thus offer the opportunity to select a new market equilibrium, more competitive than the one following the infringement, but also, in some circumstances, more competitive than the one existing prior to the infringement. This understanding of 'optimal' remedies seems in conflict with the dominant views in both public and private law on the purpose and the scope of remedial action. What is more important in an economically-oriented competition law is the fit between the remedy and the theory of harm advanced in the specific case. However, if the principle of proportionality requires a close fit between the harm and the remedy, determining the nature of that fit (functional, instrumental) is crucial as to the possibility of adopting prophylactic remedies.

This is not always an easy thing because of the inherent uncertainty in some economic theories of harm. For instance, one may take the example of a leveraging theory of harm, which has been perceived by some as problematic only if the transfer of power from one market to another establishes two monopolies that generate more monopoly profits than a single monopoly (so the single monopoly profit does not apply in the specific case), thus resulting in economic damage (reduction of output). However, in the digital economy, the motivation behind monopoly leveraging activities may be a reduction in competition over time, rather than in order to achieve an immediate or medium-term profit in product markets, if one embraces a dynamic theory of market foreclosure that also takes into account the way leveraging may affect the market evaluation of the company by financial markets. Many large firms are more intent on maximizing their

total output, sales, or growth rates in order develop network and learning effects, or increasing returns to scale, that are highly valued by financial markets, rather than in order to increase their profits short-term in product markets. Hence, defining the competition law problem as leveraging does not provide us information on the limits of remedial discretion as such, because of the different meanings this doctrine may take and the different ways the competition problem identified can be framed.

At a more abstract level, traditionally competition law is perceived as adopting a business tort law model in which the competition problem identified is somehow causally linked to a conduct, or conducts, found to constitute a competition law 'wrong'. This conceptualisation may easily hold in the context of a competition law focusing on the simple economics focusing on the effects of a specific conduct on a relevant market, but one may raise questions if it still holds in the context of the complex economics of the digital era. Applying competition law problems only to deal with harm identified in a specific relevant market may be criticised as 'standing under the streetlight': it certainly shines light, but not where we should be looking at. One may give the example of competition law infringements in multi-sided markets settings, where the remedy may have unintended consequences at the other sides of the market. The inadequacy of the current conceptualisation of competition law remedies and of the business tort model of competition law becomes clearer if one realises that the digital economy is forms a complex system where different autonomous components interact, and where the outcome of that system is not simply the sum of the underlying parts but is characterised by linearity in the way the elements of this complex system give rise to overall patterns of emerging behaviour. Indeed, these systems are characterised by increasing returns to scale and network effects, path dependence, feedback processes, leverage points, tipping points. Enforcing competition law in a complex economy requires some wider remedial discretion. This will still be framed by the competition law problem identified, if one is to stay within the scope of the business tort competition law enforcement model. However, it should also aim to remedy the indirect or likely effects the anticompetitive conduct may have contributed to in realizing. The measure of the causal link required is of course an issue for discussion. One may refer to the quite simplistic model of the counterfactual reasoning that will enable the decision-maker to build a counterfactual dependence between the world with the competition law violation and the world without it. Others may go further and refer to the structural equation models used in econometrics, which rely on complex mathematical terms that describe the agents' interactions to frame the discretion of competition authorities. Finally, one may refer to complex systems methodologies that visualise the links between the various agents, for instance through agent-based modelling, thus helping to determine the causal narrative for identifying the competition law problem that would limit the remedial discretion.

A complex economics perspective is not necessarily going to change the type of remedies, behavioural or structural, that may be adopted. It can, however, have important implications on the remedial strategy followed in specific cases. In conclusion, in view of the permanence of network effects, tipping effects and winner takes most competi-

tion in certain market configurations, it is difficult for the theory of harm, even narrowly defined, to serve as an adequate limit to remedial discretion. Most often, a competition law remedy adopted in such context may affect the way the specific economic sector or broader industry will develop in the years to come. Hence, the simple business tort model of competition law remedies may be inadequate and remedial discretion should be more significant. One may ask here the question of the institutional capability but also the checks and balances available in order to adopt remedies in such a context. Should we adopt more frequently structural remedies that would provide a more drastic solution to the immediate competition law problem? (see 5.6.2.2.). However, in markets with significant network effects it might be difficult to transform the competition game from competition *for* the market to competition *in* the market. Should we abandon the adjudicatory model and move towards a regulatory model or a structural adjudication model that would focus on the prevention of competition harm? (see 5.6.2.3.)

This is not of course a recent challenge for competition law. One may refer to some of the archetypical competition law cases regarding remedies, such as the IBM 1956 consent decree and the 1956 Bell System consent decree. These consent decrees, in particular the IBM one regulated the computer industry from 1956 until 1996, providing the opportunity for the development of the hardware and software sector in the U.S.

The IBM case provides a quite complex interplay of various remedies, of both behavioural and structural nature: prohibitions of bundling, FRAND terms, non-discrimination clauses, prohibition of restrictions of competition in aftermarkets. But more remarkably, an important feature of this remedial package adopted in this case was that seven years from the date of entry of the Final Judgment, IBM was ordered to divest itself of such part of its then existing capacity for the manufacture of tabulating cards as may then be in excess of 50% of the total capacity for the manufacture of tabulating cards in the U.S.. IBM was also prohibited from making any acquisition in related markets that would have enabled it to leverage its power in adjacent markets.

Almost similar remedies were imposed on January 24, 1956, by the Federal district court in New Jersey for the Bell System, the research subsidiary of AT&T and Western Electric, the vertically integrated monopolistic provider of telecommunication in the U.S., which was also ordered to license all its patents for free. This decree settled a 7-year old antitrust complaint that sought to break-up the Bell System. As a consequence of the consent decree, 7,820 patents or 1.3% of all unexpired US patents became freely available to all U.S. companies. Most of these patents covered technologies from the Bell Laboratories, the research subsidiary of the Bell System, which was arguably the most innovative industrial laboratory in the world at the time. Researchers at Bell Labs were responsible for ground-breaking innovations, such as the transistor, the solar cell, and the basis of the cellular phone technology. The decree also barred the Bell System from engaging in any business other than telecommunication. This led to an important diffusion of innovation. Recent economic research by Watzinger et al. has found that compulsory licensing predominately increased innovation by start-ups¹⁴³⁶. More than

1436 M. Watzinger, T. Fackler, M. Nagler, M. Schnitzer, How Antitrust Enforcement Can Spur Innovation: Bell Labs and the

two thirds of the increase in follow on innovation after compulsory licensing was driven by young and small companies and individual inventors unrelated to Bell. According to the same research, start-ups and individual inventors increased follow-on innovation by 20% while for large and old companies the increase was only around 5%¹⁴³⁷. The consent decree also led to a decrease in patenting by the Bell System, but this effect was not large enough to dominate the increase of patenting of other companies¹⁴³⁸. Furthermore, Bell shifted its research program to concentrate more on communication research, the only business Bell was allowed to be active in. However, the same economic research also notes that as Bell was not subject to structural remedies it was able to effectively exclude competitors in telecommunication because it controlled not only the production of telephone equipment but was – in the form of the Bell operating companies – also its own customer¹⁴³⁹. This was noted by the Sub-Committee on Antitrust of the US Congress, which heavily criticised the Bell decree¹⁴⁴⁰. The research concluded that foreclosure decreases innovation and that compulsory licensing is not sufficient without the adoption of supporting structural remedies. Hence, it seems that access to technology through compulsory licensing alone does not stimulate market entry and innovation, unless there is sufficient access to the product market as well.

What is remarkable in these cases is the importance that the future development of the industry played in the design of appropriate remedies and the impact it exercised on the future development of the industry. Because of network effects and path dependence, competition law remedies played an important role in opening a number of markets to competition and allowing start-ups to develop, beyond looking to the simple effects these remedies had on the consumers of the relevant market. May be these cases could provide some interesting insights on an adequate way to think about competition law remedies, that would take into account the polycentric dimension of competition law in a complex economy. They may also reinforce our conclusion in Chapter 4 that competition law remedies should be integrated in a broader framework of institutional action on digital markets (the toolkit approach).

5.4.2.2. The use of structural remedies and break ups: the past as present

Breaking up the big digital platforms has been a topic of fierce discussion in recent years. This is not the first time that structural remedies, such as a break up, have been considered as the appropriate competition law remedies. The two archetypical cases

1956 Consent Decree (February 27, 2017). CESifo Working Paper Series No. 6351. Available at SSRN: <https://ssrn.com/abstract=2938960>.

1437 Ibid.

1438 Ibid.

1439 Ibid.

1440 Ibid (noting that the final report of the Committee issued in 1959 ‘pulled the decree to pieces’. As it is observed in the Congress’ report, ‘the consent decree entered in the A. T. & T. case stands revealed as devoid of merit and ineffective as an instrument to accomplish the purposes of the antitrust laws. The decree not only permits continued control by A. T. & T. of Western, it fails to limit Western’s role as the exclusive supplier of equipment to the Bell System, thereby continuing monopoly in the telephone equipment manufacturing industry’).

are the break up of AT&T in 1956 and the attempted break-up of Microsoft in the early 2000s. While there is a widespread agreement that the break-up of AT&T was a quite successful remedy that brought overwhelmingly positive results, there has not been a consensus as to the envisaged break-up of Microsoft. The choice of a structural remedy therefore depends on a careful cost benefit analysis, not only of the competition law problem the remedy aims to cure, but also of the internal organisation, governance and characteristics of the undertaking in question.

The seminal case for a break-up imposed by antitrust law is AT&T. The company was divided into the long-distance company (AT&T), and seven regional operating companies, each of which remained a regulated local telecommunications monopoly until 1996. The destruction of AT&T's long-distance monopoly encouraged competition, which brought sharply lower prices and immense consumer benefits¹⁴⁴¹.

In *US v. Microsoft*, Judge Jackson adopted the plaintiff's remedies proposal and imposed a breakup of Microsoft into two 'Baby Bills'¹⁴⁴² an operating systems company which would inherit all the operating systems software, and an 'applications' company with all the remaining software assets. Cash and securities holdings of other companies held by Microsoft would be split between the resulting entities. Bill Gates and other officers of the company would not be allowed to hold executive and ownership positions in both of the resulting companies.

In arguing for the break-up, the government (and the judge) put forward a number of reasons. 1. That they considered the repeated violations of antitrust law by Microsoft as an indication that Microsoft would not follow any conduct or contractual restrictions; in fact, in some informal remarks, government officials believe that they were "tricked" by Microsoft in settling the 1995 case with terms that Microsoft was able to exploit; 2. That the lack of remorse by Microsoft's executives was a clear indication that Microsoft "could not be trusted" to implement any other remedy; 3. That the breakup was a "surgical cut" that would create the least interference with business; 4. AT&T and the rest of the telecommunications industry benefited from AT&T's breakup, and so should Microsoft and the software industry; after all both industries have network effects; 5. The breakup would eliminate the incentive for vertical foreclosure; and 6. The breakup would reduce the "applications barrier to entry" since now the applications company might write popular Microsoft applications (such as MSOffice) for other platforms. The government failed to show that the proposed (and later abandoned) breakup was the appropriate remedy. None of the affidavits in the remedies phase even approach a discussion on evaluating alternatives. Additionally, a few weeks before Judge Jackson's decision, under the supervision of Judge Posner the government and Microsoft had reached a compromise that imposed only conduct remedies.

1441 See the assessment of M. Watzinger, T.A. Fackler, M. Nagler, & M. Schnitzer, How Antitrust Enforcement can Spur Innovation: Bell Labs and the 1956 Consent Decree, (January 2017). CEPR Discussion Paper No. DP11793, available at SSRN: <https://ssrn.com/abstract=2904315>.

1442 This is a word play on "Baby Bells" that came out of AT&T and the first name of the co-founder and then CEO of Microsoft, Bill Gates.

There are a number of key differences between the two companies and their competitive situations. These differences make it likely that a Microsoft breakup, besides harming Microsoft, would have harmed consumers and the computer industry. In 1981, AT&T was a 100-year-old regulated monopoly with many layers of management. For historical reasons, the local phone companies within the old AT&T, such as New York Telephone, were managed separately from the “long lines” division. Thus, it was not difficult to separate the divisions since they functioned on many levels as separate companies. AT&T also had an abundance of managers to help cope with the breakup. By contrast, Microsoft was at the time a young, entrepreneurial company run by few top executives, and its divisions were fluid. During the 1980s (the first decade of its existence) its growth was mainly organic, M&A activity intensifying from 1994 and on (and really in the 2000s), as Microsoft since its foundation has acquired around 200 companies, in average 6 companies per year on different sectors of the ICT business, with 178 of these acquisitions being made after 1992¹⁴⁴³. This means that a break-up would have posed significant managerial problems and would have severely reduced the company’s flexibility. Finally, AT&T was a regulated utility, and regulation guaranteed that the companies emerging from the breakup stayed interconnected. In contrast, the Microsoft breakup would have likely led to incompatibilities and further loss of efficiency. USDOJ’s two-way breakup plan was premised on the hope that an autonomous applications company would create a new operating system to compete with Windows. But at trial it was stipulated that more than 70,000 applications run on Windows, creating what the government called “the applications barrier to entry” in the operating-system market. The new applications company, however capable, seemed unlikely to be able to singlehandedly create a successful rival operating system in short order.

The breakup of Microsoft, first proposed by the government, imposed by Judge Jackson, and, after the DC Court of Appeals decision not pursued by the government, would have had detrimental effects. First, the breakup was likely to result in higher prices. If USDOJ was correct and Microsoft kept its OS prices low so that it can exercise its monopoly power in the adjacent browser market, the post-breakup Baby Bill that would inherit the operating system would have no incentive to keep the price low. The OS Baby Bill would no longer have the incentive to disadvantage any applications companies. Thus, if USDOJ’s theories were correct, the OS Baby Bill would exercise its monopoly power and raise the price of the operating system to the detriment of consumers. If USDOJ was correct and Microsoft had significant monopoly power because of the “applications barrier to entry,” higher prices would be the direct result of the breakup. Second, as explained earlier, the breakup would likely eliminate the efficiencies that made Microsoft a flexible and formidable competitor. A breakup would likely temporarily eliminate the incentive for interference from OSs to applications and vice versa. Of course, the same can and has been accomplished by conduct restrictions without the cost and the disruption of

1443 See the discussion in A. J. Lopez Giron & P. Vialle, A preliminary analysis of mergers and acquisitions by Microsoft from 1992 to 2016: a resource and competence perspective, 28th European Regional Conference of the International Telecommunications Society (ITS): «Competition and Regulation in the Information Age», Passau, Germany, July 30 – August 2, 2017, available at <https://www.econstor.eu/bitstream/10419/169462/1/Giron-Vialle.pdf>.

a breakup. Moreover, the district court's breakup proposal did not impose permanent restrictions on the post-breakup functions of the resulting companies. The OS and the applications Baby Bills would have been able to enter into each other's business soon after the breakup. It is very likely that a few years after such a breakup, one of the resulting companies would dominate both markets in view of the network effects.

In exploring the possibility of a break-up one needs to take into account the fact that digital markets increase the risk and costs of abuses, as platforms are critical innovation catalysts to economies and conduct remedies do not adequately address the problem¹⁴⁴⁴. The cost of type I and type II errors is also relatively more complex in the digital economy, because of the important cascade effects and the possible impact on innovation that market tipping may generate¹⁴⁴⁵. Hence, the usual caution of competition authorities for committing type I errors (false positives) is not warranted.

Each of the Big Tech that have been at the centre of attention, such as Google, Apple, Facebook, Amazon, Microsoft, Alibaba, Baidu, Tencent, JD.com, presents proper characteristics and has a distinctive history, and from this perspective one should not venture in providing broad recommendations that would apply to all. One of the main concerns put forward by those asking for a structural separation is that platforms should be prohibited from taking advantage of their dual role as platforms/marketplace operators and also presence in markets more 'open' to competition.

In a recent paper Lina Khan argues that Amazon exploits a dual role as marketplace operator and merchant by instituting policies that benefit Amazon when it sells products, for example, securing greater control over brands and pricing. Amazon additionally appropriates information related to sales of merchants' products. With regard to the first category of abuse, Amazon takes the default position in product lists even when other goods sell at lower prices. The default position accounts for almost 82 percent of Amazon sales¹⁴⁴⁶. For the second category, Amazon can incorporate into its operations information beyond sales. The information may relate to clicks, or how price changes, product images, and videos altered consumers' response to listings¹⁴⁴⁷. The information gleaned from Alexa also affects product strategy. To build an ecosystem around Alexa,

1444 See, inter alia, L. M. Khan, *The Separation of Platforms and Commerce*, (2019) 119 Columbia L. Rev. 973.

1445 The issue is discussed in great detail in the J. Cr  mer Y.-A. de Montjoye & H. Schweitzer, *Competition Policy for the Digital Era* (Final Report, OPOCE, 2019), available at <http://ec.europa.eu/competition/publications/reports/kd0419345enn.pdf>) (hereinafter European panel of experts Report), 4 & 50-52, which concludes (at 5), ' The specific characteristics of many digital markets have arguably changed the balance of error cost and implementation costs, such that some modifications of the established tests, including allocation of the burden of proof and definition of the standard of proof, may be called for. In particular, in the context of highly concentrated markets characterised by strong network effects and high barriers to entry (i.e. not easily corrected by markets themselves), one may want to err on the side of disallowing potentially anticompetitive conducts, and impose on the incumbent the burden of proof for showing the pro-competitiveness of its conduct. This may be true especially where dominant platforms try to expand into neighbouring markets, thereby growing into digital ecosystems, which become ever more difficult for users to leave'. We agree with these conclusions.

1446 L. M. Khan, *The Separation of Platforms and Commerce*, (2019) 119 Columbia L. Rev. 973, 987-988. (Third party vendors still account for over 50 percent of sales on Amazon).

1447 Ibid., 992.

Amazon created a \$100 million fund to sponsor voice-technology startups. Khan says that Amazon uses the fund as cover to steal product ideas¹⁴⁴⁸. Alexa further selects Amazon skills as the default choice¹⁴⁴⁹.

Turning to Alphabet, Khan writes that Google accounts for all of Alphabet's operating income, \$36.5 billion in 2018, and that U.S. consumers use Google for 88 percent of searches, and 95 percent of mobile searches¹⁴⁵⁰. She focused on discussing the 2011 FTC investigation of Google, which considered whether Google privileged its own sites. It also evaluated whether Google scraped information from third-party websites to enhance the quality of its vertical sites. Utilizing contract terms to effectuate this act, Google coerced website publishers to agree to license agreements that granted Google access to their data feeds. To appear within search results, third-parties had to agree to the terms. FTC staff concluded that the scraping practice inhibited incentives to invest in, and create, valuable content. The Commissioners nevertheless settled¹⁴⁵¹.

Next is Facebook. Khan isolates the abuse as appropriating information, and she identifies the following victims who both rely on Facebook's platform while competing against Facebook: application developers and online publishers¹⁴⁵². Concerning developers, Facebook basically excludes apps that it decides to manufacture. It has written a platform policy that prevents developers from utilizing its APIs to support a product that Facebook considers "core" to its platform. Voxer experienced this purported abuse¹⁴⁵³. Concerning publishers, they need access to Facebook users to make advertising more attractive. Facebook sells to the same advertisers, and it can appropriate information about the publisher's readers to sell advertising directed at the same readers at a fraction of the price that the publisher charges¹⁴⁵⁴.

In mentioning Apple, Khan looks primarily to Spotify's EU complaint. Spotify states that Apple charges it a 30 percent fee for in-app purchases, but Apple levies the fee selectively. Apps that Apple manufactures and apps that do not compete directly with Apple, for instance, Uber, do not need to pay the fee. Beyond price, Spotify complains that Apple does not permit it to communicate or market services directly to Apple users. The third category relates to refusing apps access to the platform because they replicated functionality of core Apple apps. Apple removed a digital wellness app from its platform after introducing its own version¹⁴⁵⁵. The last category concerns a "release radar". Apple designed this technology to monitor apps that may threaten Apple's business interests¹⁴⁵⁶.

1456 Ibid., 1006-1007.

Khan argues that competition law should prohibit market operators from vertically integrating and competing in separate markets¹⁴⁵⁷. Note that this was a remedy that has been successfully applied in the context of the AT&T consent decree in 1956, which had barred the company competing in industries other than telecommunications and imposed the company the obligation to license its patents to other companies at reasonable fees, spurring a wave of innovation in the development of ICT. Such an approach was also followed in IBM, which in contrast to AT&T was not a regulated monopoly. The company was banned from vertically integrating forward into the 'service bureau' business and sell the services for computers rather than computers themselves. Arguably, this ban may have helped in the emergence of a separate computer services industry, and the vertical specialisation of the computer software value chain, on the basis of a structured set of standards enabling the integration of multiple products and functionalities produced by firms in the various vertical layers of the industry¹⁴⁵⁸. Khan claims that until the 1970s, regulatory agencies did not permit dominant gatekeepers to compete with entities seeking access to the gatekeeper's facilities¹⁴⁵⁹ and, on this basis, argues for restrictions that prevent entry into adjacent markets, defined as involving 'a successive stage of production or distribution'¹⁴⁶⁰. Federal and state governments restricted line-of-business expansion utilizing a variety of methods, including corporate charters, regulatory regimes, and antitrust law. The provisions covered sectors both exhibiting monopoly power and sectors critical to an economy. Government oversight focused on ensuring reliability and non-discrimination. For further support, Khan refers to language in some old cases of the Supreme Court stating that vertical integration can 'clog' competition, preventing 'a fair opportunity to compete'.¹⁴⁶¹ Khan noted that the Supreme Court determined that only divestiture could remedy the harm that the acquisition caused. In digital markets, she highlights the entry barriers of network effects and unequal access to data¹⁴⁶².

Such remedy eliminates the incentive of the platforms to commit an abuse, the functional goal for such remedy being not only economic efficiency or consumer welfare gains (as narrowly or broadly these are defined) but also broader considerations of fair competition and system resilience, media diversity, and administrability of the system. Some of these goals are linked to welfare economics but several other serve broader objectives¹⁴⁶³.

However, the dual role of platforms does not exhaust the concerns expressed by the proponents of a break-up. Indeed, in addition to acquiring nascent rivals, which may

be a concern that could be addressed pre-emptively by reinforcing the standards of intervention of merger control for reasons of preservation of potential competition, the intensity of M&A transactions led by the platforms prevents investment and innovation. Despite the scale of venture capital funding, recently surpassing \$100 billion for the first time since the dot-com era, the number of angel investments has fallen since 2015. Start-ups have lower chances of acquiring initial financing¹⁴⁶⁴. Khan sites anecdotal evidence that investors have little desire to risk money on firms competing with a “core functionality” of Google, Facebook, or Amazon¹⁴⁶⁵. In a vertical platform context, Khan defines harm to competition as platform conduct that “reduces investment and entrepreneurial activity by independent parties,” causing loss to innovation¹⁴⁶⁶.

To guide “platform policy” and enforcement, Khan sees value in promoting network neutrality and common carriage principles as supporting innovation¹⁴⁶⁷. The Internet Protocol enables developers at a network’s edge to design new services without needing to seek permission from network operators. The protocol itself derives from common carriage principles, which mandate that regulated entities treat equally situated parties in the same manner. At its core, common carriage promotes nondiscriminatory public access and indifference to the goods that an infrastructure carries¹⁴⁶⁸.

This support for a structural remedy may also be linked to the relatively strict US antitrust standard for discriminatory refusals to deal, under Section 2 of the Sherman Act. As *Trinko* requires the discriminatory refusal to deal to create a new monopoly or strengthen an existing one, this requirement drains the claim of any vitality¹⁴⁶⁹, and therefore leave a prohibition of vertical integration the only possible choice, if of course some other anticompetitive conduct may provide the opportunity to adopt antitrust law remedies. This is also essential as, according to Khan, there is a gap in the current US law, which generally does not support exclusionary conduct cases based on information appropriation, because of the evidentiary difficulty of showing anticompetitive effects in innovation terms, as the consumer welfare standard favours effects cognizable in price and output terms¹⁴⁷⁰. These are of course idiosyncratic characteristics of the U.S. antitrust regimes and may not be of relevance for other competition law regimes where the antitrust provisions against exclusionary conduct, in particular discriminatory refusals to deal and exclusionary discrimination, have more teeth. The EU competition law regime comes as an example.

With regard to the institutional setting of the separation regimes that may emerge, Khan explores those applied to railroads, bank holding companies, television networks, and telecommunication carriers and notes that agencies and courts implemented the re-

gimes twice by statute, twice by agency regulation, and once as an antitrust remedy¹⁴⁷¹.

To highlight the choice of a regulatory framework, she explores, among others, the separation regimes resulting from the enactment by Congress a hundred years ago of a “commodities clause” that prohibited railroads from carrying items that it had produced or in which it may have had any interest. The FCC instituted a similar provision against television networks by regulatory means, expressing concern about programming practices. The following two dynamics justified regulation in this case. First, the major networks offered access to nearly all viewers, from which they acquired monopsony power. That power enabled the networks to purchase programming on terms that materially disfavoured producers. Second, the FCC found that the networks also benefited from monopoly power that they exploited to refuse selling programs to independent stations, and to favor network affiliates by granting advantageous syndication rights. The harm that the FCC underlined related to limiting the number and variety of programs that the public could view, or curtailing program diversity. The FCC’s ultimate order structurally prevented the networks from entering the production and syndication markets¹⁴⁷².

Referring to another FCC investigation, Khan depicted similar provisions in the telecommunications field. Telecommunication carriers had sought to enter data processing, a move creating concern that they would utilize control over infrastructure to inhibit competitors in the data processing market. During the course of several proceedings, the FCC enforced degrees of separation between the two markets. At first, the regulated communication carriers could compete in the data processing market only by forming a separate subsidiary¹⁴⁷³. Later, the FCC altered its position from structural separation to mandating unbundling and equal access¹⁴⁷⁴.

Khan identifies six additional reasons justifying structural limits: (1) removing conflicts of interest, (2) protecting against cross-financing that would expand existing dominance, (3) maintaining system resiliency, (4) promoting diversity, (5) not allowing the growth of market power, and (6) advancing administrability¹⁴⁷⁵.

Relating to preserving system resiliency, Khan primarily points to the public interest in preserving stability and protecting against disruption to justify separation. Indeed, when a single system crashes, effects could cascade. Khan notes how, several years ago, a single outage at Amazon caused Netflix, Reddit, Business Insider, and several other websites ‘to crash for five hours’: Monoculture creates security vulnerabilities, increasing the incidence of malware or hacks¹⁴⁷⁶. Relating to diversity, separation promotes more vibrant competition between producers that serve to promote diversity¹⁴⁷⁷. Khan cited the Comcast-NBC merger, about which the government worried that Comcast might fa

your NBC programming. Khan stated that this concern has proved valid, since Comcast has discriminated against rival content¹⁴⁷⁸. Relating to prioritizing administrability, Khan noted a repeated concern by the FCC that parties harmed by a dominant undertaking infrequently will know when the harm has occurred. Structural remedies promote deterrence¹⁴⁷⁹.

Although structural separation may be an adequate remedy in the U.S. context, and we remain agnostic as to this issue, to the extent that a separation regime may affect a company whose main assets are overseas, this will raise important concerns, regarding international comity, and should these been non-influential factors in establishing prescriptive jurisdiction, may raise issues of enforceability of remedies, in particular for authorities of developing countries, unless some arrangement is reached. These concerns were examined in Section 5.4.2.2.

Assuming that such separation regimes were possible, this would call for the establishment a general framework for separating platforms and commerce. This broader regime may be put in place, with the view that some entities serve critical gatekeeper functions in the digital economy¹⁴⁸⁰. This would apply to platform businesses. Khan would define platforms by evaluating the following factors: (1) the extent an undertaking operates as a central exchange for transacting goods, (2) the extent an undertaking is necessary for productive uses downstream, and whether downstream entities can access substitutes, (3) the extent the undertaking acquires value from network effects and the type at stake, (4) the extent the undertaking operates as infrastructure for “customizable applications” by third parties, and (5) “the size, scope, scale, and interconnection of the company”¹⁴⁸¹.

Returning to broader points related to the six themes discussed previously, Khan highlights the unfairness of forcing consumers of regulated products to support entry into unregulated markets through cross financing. While acknowledging that dominant platforms do not rely on regulated rates, she expresses a parallel concern for utilizing supra-competitive profits to finance entry into a multiplicity of other markets¹⁴⁸².

There may be also other concerns, such as media diversity, that can be put forward in order to justify the imposition of a structural separation regime, the issue here being if this should be an antitrust concern, or if this should be imposed through some other sector-specific regulatory regime. For instance, Khan advances the policy of separating Facebook’s and Google’s communication networks from their advertising businesses, having previously stated that both platforms derive nearly all their revenue from advertising. Permitting the combination deprives publishers of ad revenue, and society should protect the news media¹⁴⁸³.

1478 Ibid., 1057.

1481 Ibid., 1077.

1482 Ibid., 1063.

1483 Ibid., 1068.

To determine which carriers to separate, Khan approvingly cites the FCC's previous policy of looking to operating revenue¹⁴⁸⁴. The next step would involve identifying what qualifies as distinct products or services. Khan pointed to the *Jefferson Parrish* consumer-demand test as appropriate to evaluate distinct functionalities. Regulators would have the capacity to determine, over time, whether apps contributed to basic functionality, and whether the benefits of integrating features offset potential harms to innovation¹⁴⁸⁵. Khan admits a separation regime may "sacrifice certain cost savings, resulting in higher prices." Yet enforcement authorities can weigh losses in static efficiency against innovation benefits, just as they can weigh losses in platform innovation against increases in "complementor" innovation¹⁴⁸⁶. The main alternative to such proposal is a standalone non-discrimination regime, but in Khan's view, it risks ineffectiveness, and she claims the Google-Shopping case as an illustration of how a non-discrimination approach has not altered the underlying market dynamics¹⁴⁸⁷. Khan argues that there is an incentive for dominant platforms to exclude complementors when the act would enable it to price discriminate¹⁴⁸⁸. Referencing another economic factor separating digital platforms, in this case Google, preferring its own sites help lock users within its ecosystem, permitting Google to secure more data and sell more ads at higher prices¹⁴⁸⁹.

Such proposals have of course to be assessed with caution and, as we explained above, need to be properly evaluated with regard to the characteristics, organisation and history of each specific undertaking that may be subject to such drastic remedies. It also raises questions as to the appropriate institutional setting for imposing such a remedy, and the capacity of jurisdictions, developed or developing, to mandate the structural separation of undertakings with headquarters and productive assets in other jurisdictions, and in particular in jurisdictions with a significant political and economic clout. The risk that such remedies may be considered as motivated by protectionist intent, rather than by genuine competition law concerns, could be a factor that may lead to tensions and could backfire. In the absence of a global competition law regime, there is not much that can be done at this level, other than probably intensifying cooperation and the exchange of information between competition authorities and also between competition authorities and courts. An important issue is also if such remedies should be adopted by statute or rulemaking, or through remedies. For instance, the US FTC could act under Sect. 5 of the FTC Act to sketch a separation regime through rulemaking¹⁴⁹⁰. Such a possibility does not exist for competition authorities in all jurisdictions.

However, separation can take different forms and need not be structural. Some 'light-touch' separation may be achieved by policies mandating digital platforms not to use personal data that has been harvested by the members of their ecosystems unless they

have the explicit consent by their users, or to ensure that more protective to privacy personal data policies of companies that have been acquired by a large digital platform stay, even after the acquisition, and are not replaced by the less privacy-oriented policies of the acquirer. This 'data separation' may be for instance quite easily implemented and could reduce the data advantage that some platforms have in view of the time people spend on their various ecosystems (see Chart 5.1.). If one looks carefully to the time spent with the dominant digital platforms' ecosystems, it appears that establishing barriers to the use of data across the various members of the ecosystem may provide reduce the barriers that new entrants because of the data advantage of the digital platforms, to the extent also that this advantage was not acquired through organic growth but through the acquisition of popular rivals that could have otherwise acted as competitive threats to the dominant position of the platform.

For instance, following the acquisition of WhatsApp from Facebook, in August 2016, WhatsApp updated its privacy policy to allow for linking WhatsApp users' phone numbers with Facebook users' identity. Hence, the previous statement at the time of the assessment of the merger was proven to have been misleading. Indeed, at the time the merger transaction was assessed, Facebook had offered assurances to the Commission, both in the notification form and in a reply to a request of information, that it would be unable to establish reliable automated matching between Facebook users' accounts and WhatsApp users' accounts. The Commission imposed a €110 million fine on Facebook for providing misleading information about the WhatsApp merger¹⁴⁹¹. Furthermore, by

¹⁴⁹¹ Facebook/ WhatsApp (Case COMP/ M.8228) Commission Decision (17 May 2017), available at http://ec.europa.eu/competition/mergers/cases/decisions/m8228_493_3.pdf.

decision of 6 February 2019, the German Federal Cartel Office (Bundeskartellamt) decided that Facebook will in future be prohibited from merging user and device-related data collected by its own services (Instagram, WhatsApp, Masquerade and Oculus) with the user's Facebook account without the user's voluntary consent. This also applies to data collected by Facebook Business Tools on third-party websites. Facebook's way of collection data with those services was held to constitute an abuse of exploitation in relation to the users as well as an exclusionary abuse in relation to the competitors violating § 19 para. 1 of the Act against Restraints of Competition (GWB).

5.4.2.3. Preventive structural adjudication

Remedial discretion is an instance of adjudication and, as such, it is subject to the inherent limits of adjudication, as a separate form of social ordering from those of contracts/negotiation, managerial/administrative discretion or legislation¹⁴⁹². Should remedial discretion move beyond the limits of adjudication and cross over the —territory of regulation or contractual governance, the decision-maker should adapt, by developing legitimacy-building tools that would emulate those used in the context of these other forms of social ordering. The participation in the remedial process of the interests affected constitutes an important source of legitimacy for managerial/administrative discretion. Consequently, if competition law remedies move closer to regulatory ones and therefore cross the limits of adjudication, they should give rise to increased participatory rights of the interests affected, including interests others than the parties to the dispute. Competition law enforcement may fit the dispute resolution model if for instance we have a dispute between well-defined parties and the effects of the specific conduct concern one, or more, specific relevant markets.

The adjudication of polycentric disputes is however problematic because the complexity of the dispute and the range of those affected, which sometimes it is difficult to foresee, render it quite difficult to organize their participation to the dispute so as to represent their position. Informed only by the litigating parties, the decision-maker is ill-equipped to determine the impact of the decision reached on the different interests affected, with the consequence that the decision reached may negatively affect societal welfare. Indeed, some problems, such as the allocation of economic resources, for instance the capture of the surplus value generated by innovation, may indeed —present too strong a polycentric aspect to be suitable for adjudication.

In the digital economy, and because of the complexity of digital value chains, a dispute may have quite pronounced polycentric elements, in view of the cascade effects and the impact to the overall economy, as many sectors may rely on the specific digital platforms concerned. This renders the distinction with the administrative/managerial model particularly difficult at times, at a practical level, although there is some value in thinking of the two (adjudication and administrative managerial model) as ideal types forming a *continuum* with regard to the —appropriate degree of discretion and consequently the

1492 For a discussion, see I. Lianos, *Effective Competition Law Remedies*, in Ph. Lowe, G. Monti, M. Marquis (Eds.), *European Competition Law Annual 2013*, (Hart Publishing, 2016), 105.

legitimacy of the action of the institutions in charge, which is closely related to the participation of the interests affected. Put simply, the more competition law moves towards the regulatory/managerial model, and —structural adjudication comes close to that, the more it should integrate the legitimacy-building mechanisms of such model, with an enhanced participation of the entities subject to the remedies as well as of all those whose interests may be affected (i.e. consumers, competitors in related markets, interests vicariously represented by organizations and citizen's groups, i.e. environmental associations). The triadic model of dispute resolution, limited to the parties and the adjudicator, needs to give way in circumstances of significantly polycentric disputes to the more inclusive model of —structural adjudication in order to preserve the legitimacy of competition law enforcement and its continued relevance and appeal to society at large.

Remedies adopted in the context of commitment decisions often fit closely to the model of —structural adjudication: being prospective by nature and aiming to the elimination of any potential threat to the value of competition, by proceeding to the re-structuring of the organization involved in the violation of competition law, and not just the issuance of a prohibition aimed at some specific act or conduct. However, they intervene *ex post* and in the context of the digital economy where market tipping may bring long lasting effects, this may not be the most appropriate way of action. A different option is the possibility of some competition authorities to order sector enquiries, providing them the possibility to adopt remedies, or order market investigation references, with the same effect. The aim of such market investigation or sector enquiry would be to map the possible bottlenecks and other sources of power, using the value chain methodology, before envisaging possible remedies that may tackle these problems. They will thus offer the opportunity to intervene *ex ante* and prevent any anticompetitive conduct. This has already been suggested in the Furman Report¹⁴⁹³, taking advantage of the possibilities offered by the UK regime on market investigation references¹⁴⁹⁴. BRICS competition authorities should grasp the opportunities provided by their mandate and legislative framework to use these tools when available, either on their own, or jointly with other regulators. One should note the initiative of the South African Competition Commission, which adopted in April 2019 the provisional findings and recommendations of its Data Services Market Inquiry, making plain use of the tool of market inquiries that has been significantly overhauled by the Amendment Act 18 of 2018 by way of, among other things, placing a time period on when a market inquiry should be completed and giving the Competition Commission stronger powers to address the shortcomings identi-

1493 J. Furman et al., Unlocking digital competition, Report of the Digital Competition Expert Panel (March 13, 2019), available at <https://www.gov.uk/government/publications/unlocking-digital-competition-report-of-the-digital-competition-expert-panel> 116-117 (hereinafter Furman report), (suggesting an investigation of the entire digital advertising value chain). The Report noted however that the remedies adopted in this context 'are largely static' and that 'rules imposed as a remedy following a market investigation may quickly go out of date' (p. 79).

1494 Following Part 5 of the Enterprise Act 2002. In the EU context, sector inquiries do not carry the possibility for the Commission to impose remedies, but may instead lead to the initiation of competition law proceedings under Articles 101 and 102 TFEU. Consequently, the mandate of the Commission in exercising its competition law competence is exclusively adjudicator.

fied¹⁴⁹⁵. Since this Act, the Competition Commission has the power to make binding recommendations at the completion of a market inquiry and to engage with a variety of stakeholders, thus offering a holistic perspective on the issues arising¹⁴⁹⁶.

5.4.2.4. Ex ante or ex post regulation of algorithms

Algorithms may facilitate or support collusion and, for this reason, their use sometimes may raise competition law concerns, among other issues that may be even more important costs from a social welfare perspective (ethics, discrimination, privacy)¹⁴⁹⁷. Competition concerns are principally concerned by algorithmic collusion, in particular by autonomous 'Q-learning algorithms', and algorithmic price discrimination. There have been discussions to introduce some form of *ex ante* evaluation and regulation of algorithms by an algorithmic regulator (or a competition authority) in order to screen them and assess the competition risk they pose¹⁴⁹⁸. *Ex post* auditing and sanctioning should complement these *ex ante* regulation¹⁴⁹⁹. Both these *ex post* and *ex ante* assessments should in our view be performed by specialised digital regulators, in view of the economies of scale achieved in analysing an algorithm in view of the variety of regulatory concerns they may raise, thus combining competition law screening with data protection, non-discrimination/equality and ethics screening. The role of *ex ante* and *ex post* regulation of algorithms is also examined in the Chapters dedicated to algorithmic collusion (Chapter 8) and privacy restrictions to competition (Chapter 11).

5.4.2.5. Data portability

Data portability is the right extended to digital users to move, copy and / or transfer their personal data across different platforms. This right insures the free flow of personal data and that users are not captive to a few digital platforms. This has important synergies to competition law and enforcement in the digital world where access to personal data is crucial for the development of some digital products and services in the world of multi-sided platforms with of strong network effects and lock-in effects.

Felten, J. R. Reidenberg, D. G. Robinson & H. Yu, "Accountable Algorithms", (2017) 165 University of Pennsylvania Law Review 633.

In this Section we will provide an overview of data portability right under data regulations, from global perspectives, mainly in the EU and the US as well as from the BRICS perspectives. In each section we will answer the following questions: is data portability a recognized right under the relevant national regulations? If yes, what is the national parameters of data portability? How have this right been exercised?

5.4.2.5.1. Data Portability in EU Regulations

In 2016, the European Union (the EU) adopted the General Data Protection Regulation (GDPR)¹⁵⁰⁰ to harmonize data protection laws in the EU / European Economic Area (EEA) and extend data privacy for all EU citizens inside and outside of the EU. The GDPR addresses organizations across the world that collect and process data on individuals who are physically located within an EU member state, regardless of whether they are established inside or outside the EU (extraterritoriality).¹⁵⁰¹

In particular, the GDPR specifies a number of rights to digital users, among which is data portability.¹⁵⁰² It requires all data subjects to have the right to receive the personal data concerning him or her¹⁵⁰³, which he or she has provided to a controller, in a structured, commonly used and machine-readable format.¹⁵⁰⁴ The GDPR also provides that, where technically feasible, the data subject shall have the right to have the personal data transmitted directly from one controller to another. This right however will not be applicable where the processing of the information is for the purpose of the public interest or is done in the exercise of an official authority.

The GDPR places compliance obligations on organization and requires an appointment of Data a Protection Officer (DPO) for organizations whose core activities consist of processing operations which require regular and systematic monitoring of data subjects on

1500 The GDPR replaced replaces the Data Protection Directive 95/46/EC. The regulation came into force in May 2018. See <https://eur-lex.europa.eu/legal-content/EN/TXT/PDF/?uri=CELEX:32016R0679&from=EN> (last accessed September 2, 2019).

1501 Article 3 of the GDPR. The GDPR applies to controllers and processors including “cloud storage”. See also EU, A new era for data protection in the EU What changes after May 2018, available at https://ec.europa.eu/commission/sites/beta-political/files/data-protection-factsheet-changes_en.pdf (last accessed September 2, 2019). It applies to the processing of personal data by controllers and processors in the EU, regardless of whether the processing takes place in the EU or not. The GDPR also applies to the processing of personal data of data subjects in the EU by a controller or processor not established in the EU, where the activities relate to: offering goods or services to EU citizens (irrespective of whether payment is required) and the monitoring of behavior that takes place within the EU. Non-EU businesses processing the data of EU citizens also have to appoint a representative in the EU.

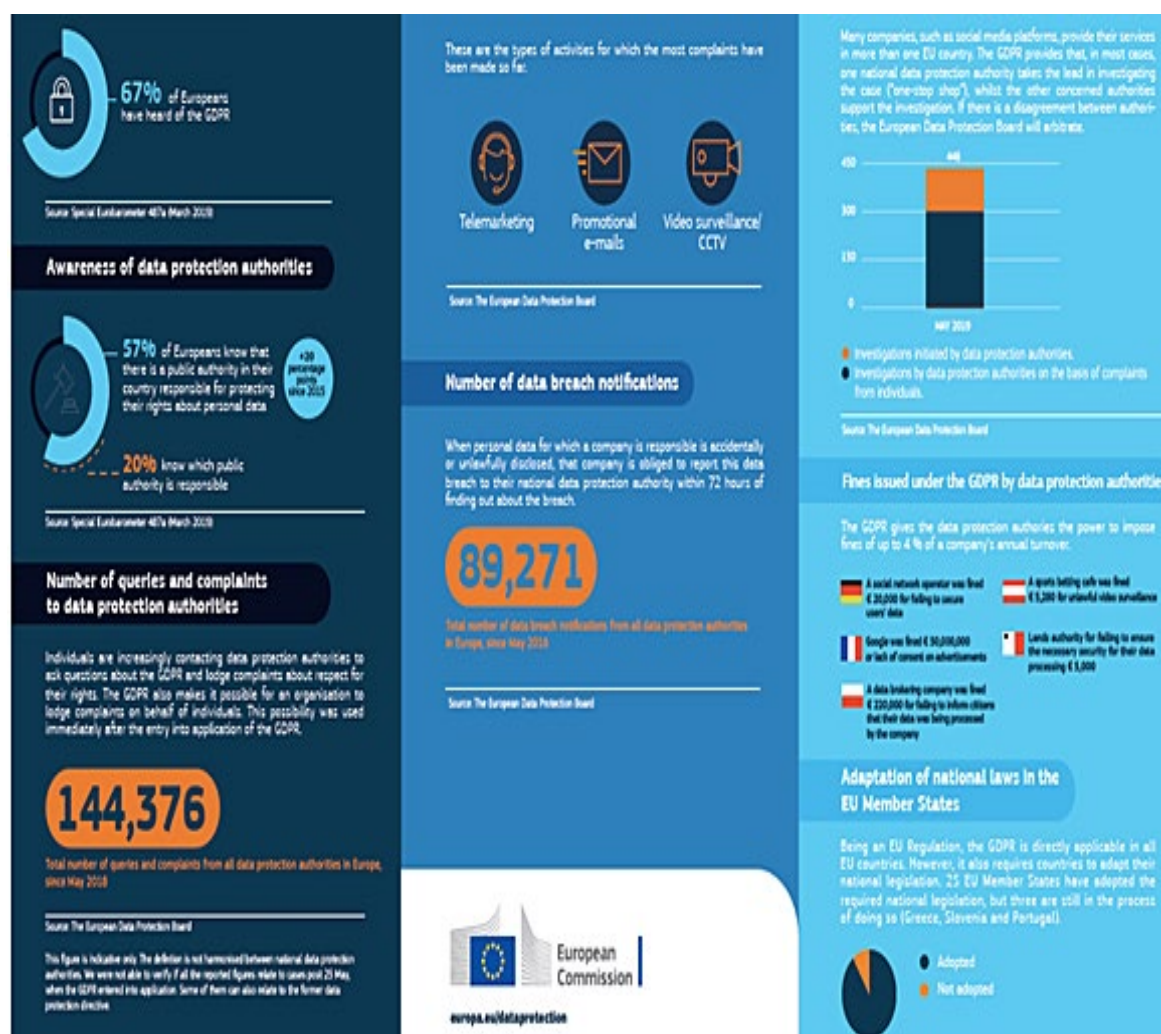

1502 Such as the right to be forgotten, breach notification, right to access, privacy by design, right to restrict data processing, right to object and the rights in respect of decisions involving automated processing and profiling.

1503 (1) ‘personal data’ means any information relating to an identified or identifiable natural person (‘data subject’); an identifiable natural person is one who can be identified, directly or indirectly, in particular by reference to an identifier such as a name, an identification number, location data, an online identifier or to one or more factors specific to the physical, physiological, genetic, mental, economic, cultural or social identity of that natural person;

1504 Controllers must make the data available in a structured, commonly used, machine-readable and interoperable format that allows the individual to transfer the data to another controller. See Article 20 of the GDPR – Right to data portability, and Recital 68 – Right to data portability

a large scale or of special categories of data or data relating to criminal convictions and offences to carry out internal record keeping requirements.

Figure 5.5. The GDPR in Numbers (May 2019)

Source: The European Data Protection Board

Non-compliance with the GDPR could result in varying consequences for the organizations addressed by the rules. These vary from a written warning, periodic data protection audits to fines of up to €10 million, or 2% of the worldwide annual revenue of the prior financial year, whichever is higher or 20€ million or 4% of an organization's annual worldwide turnover (whichever is greater), depending on the violation. The most serious penalties apply to organizations that suffer a data breach as a consequence of non-compliance. Since 25 May 2018, 30 different EEA SAs have registered a total amount of 281 cases with cross-border component in the IMI system, where the large part of the opened cases derived from complaints by individuals (194 cases) and related to related to the exercise of the data subjects' rights, to the consumer rights and to data breaches.¹⁵⁰⁵ Most recent data (May 2019) shows an increase in the number of cross-boarder cases (446). Earlier this year, the French Privacy watchdog imposed a fine of 50 million

euros on Google for lack of transparency, inadequate information and lack of valid consent regarding the ads personalization.¹⁵⁰⁶

5.4.2.5.2. Data Portability in the US

The United States has not passed comprehensive federal legislation covering privacy or data protection. It has enacted sector-specific regulation that created a form of data portability. In the healthcare domain, the Health Insurance Portability and Accountability Act (HIPAA) gave patients a federal right to access their health records. Lothar Determann, *Healthy Data Protection*, pp. 7-8 (Mar. 2019). The 2010 Dodd-Frank Act created data portability rights in financial and account information that extends to authorized third parties. Peter Leonard, *Regulatory trends and emerging practices in access to customer data, portability and data sharing in the financial services sector*, pp. 16, 28 (2017). In the last relevant sector, Congress had permitted consumers to access credit scoring information and an annual free credit report.¹⁵⁰⁷

At the state level, California has led with the California Consumer Privacy Act, which will not go into effect until January 2020. This statute creates a free right to data portability: consumers may request personal information that both online and offline businesses must provide in a format conducive to portability.¹⁵⁰⁸ By contrast to violations of the Sherman Act, only the state attorney general can enforce the statute. Businesses have a 30 day cure period to avoid civil penalties that can reach \$2500 per violation, unless intentional, permitting a fine of \$7500 per violation.¹⁵⁰⁹ In term of scope of the data portability right, California's provision goes further than Europe's equivalent requirement, since it applies to inferred data concerning an individual, which the GDPR exempts.¹⁵¹⁰ Several states have proposed or are investigating data privacy laws primarily based on the California model.¹⁵¹¹

Beyond the statutory route to data portability, U.S.A. consumers could pursue a common law right, centered in contract law. A pending Restatement of the Law on Consumer Contracts may advise courts whether to view privacy policies as contracts.¹⁵¹² The FTC however, has adopted the more strict, contract view while enforcing consumer protection law.¹⁵¹³ State attorneys general can pursue similar actions. Several federal district

courts have not found a property interest in personal information.¹⁵¹⁴ The Third Circuit tests for a property interest by looking to whether plaintiffs alleged that they intended to monetize their data.¹⁵¹⁵ The debate of whether privacy policies qualify as enforceable contract rights relates to data portability because several of the leading online platforms have self-regulated, creating data portability rights that would comply with Article 20 of the GDPR.¹⁵¹⁶

5.4.2.5.3. Data Portability in the BRICS Countries

In 2018, **Brazil** approved the General Data Protection Law (GDPL), expected to take effect in 2020.¹⁵¹⁷ The GDPL sets the rules for the use of personal data in Brazil.¹⁵¹⁸ With few exceptions, the law is expected to apply to all sectors of the economy in relation to processing of personal data.¹⁵¹⁹

The GDPL follows the GDPR in many respects such as extraterritorial application where any foreign company that has at least a branch in Brazil, or offers services to the Brazilian market and collects and treats personal data of data subjects located in the country, regardless of the nationality, will be subject to the law.¹⁵²⁰ However, among the differences between the two legislations, the definition of ‘sensitive personal data’, were the GDPL seems to go further when defining the term than the GDPR¹⁵²¹ but however allows for the commercialize of such data provided there is authorization from the public authority.

Among the rights provided under the GDPL is data portability, which access to data, rectification, cancellation or exclusion, opposition to treatment, right to information and explanation about the use of data. The GDPL also provides for the international transfer of personal data, even to countries that are not considered to have an adequate level of protection provided a specific and express consent of the data subject is obtained or if there is a guarantee, by the controller through contractual instruments such as binding corporate rules and standard clauses, that it will comply with the principles, data subject rights and the data protection regime provided by law.

1518 the LGPD is replacing and/or supplementing this sectoral regulatory framework, which was sometimes conflictive, marshy, without legal certainty and made the country less competitive in the context of an increasingly data driven society. 40 legal norms at the federal level that directly and indirectly deal with the protection of privacy and personal data in a sector-based system.

1519 such as national and public security; pure research, artistic and journalistic purposes

1520 Article 3.

1521 Article 5 II “sensitive personal data: personal data concerning racial or ethnic origin, religious belief, political opinion, trade union or religious, philosophical or political organization membership, data concerning health or sex life, genetic or biometric data, when related to a natural person”.

The GDPL also addresses the role of the data protection officer (DPO) who is responsible to insure compliance within an organization and provide guidance to staff and contractors in relation to the measures to be taken for the protection of personal data. The enforcement of the law also envisages the creation of a national Data Protection Authority (NPD), which is expected to be created by a provisional measure or proposed in a bill in the near future.

In case of violation of the GDPL, administrative sanctions may be applied by a dedicated authority which includes notices and fines, that may vary from 2 percent of the organization's turnover in Brazil in its last fiscal year, or R 50,000,000.00 (whichever is higher) per violation.

In Russia, the Federal Law No. 152-FZ "On Personal Data" (the "**PDL**") was adopted in 2006.¹⁵²² Under the PDL, personal data is defined as any information directly or indirectly related to an identified or identifiable individual including his surname, first name, patronymic, year, month, date and place of birth, address, marital, social, property status, education, profession, income, other information.¹⁵²³ The PDL includes the concept of "data operator", which is defined as a person that organizes or carries out the processing of personal data and determines the purposes of processing.¹⁵²⁴ It has been reported that Russian authorities now apply a broader interpretation of Personal Data such as the Federal Service for Supervision of Communications, Information Technology and Mass Media (Roskomnadzor) actions against telecom companies for selling user activity data to advertising companies, while the Ministry of Communications (the regulator in the area of Personal Data) has issued non-binding clarifications, where it concluded that personal mobile phone numbers and emails addresses by themselves constitute Personal Data.¹⁵²⁵

There is no extraterritoriality under the PDL; it applies to any legal entity, including any foreign entity with a legal presence in Russia, that collects personal data in Russia. In addition, the PD Law provides for local storage requirement, which applies to any data operator that processes the personal data of Russian citizens, regardless of its jurisdiction.¹⁵²⁶

The Federal Service for Supervision of Communications, Information Technology and Mass Media (Roskomnadzor) is the data protection authority. In 2018, the Roskomnadzor carried out 728 inspections¹⁵²⁷, revealed 1882 violations of the PDL and imposed ad-

1526 Amendments introduced in 2014 <https://gettingthedealthrough.com/area/52/jurisdiction/26/data-protection-privacy-russia/>.

1527 K. Andreeva, Anastasia Dergacheva and Vasilisa Strizh, Hot Topics In Data Privacy Regulation In Russia, November 27, 2018 <https://www.morganlewis.com/-/media/files/publication/presentation/webinar/2018/hot-topics-in-personal->

ministrative fines for processing of personal data without proper legal grounds, failure to obtain a written consent of an individual, failure to inform an individual on the processing of his personal data – warning or, failure to publish a personal data processing policy and failure to file a notification to Roskomnadzor.

The data protection legislation however still lags behind compared to EU standards where new categories of personal data such as genetic data are lacking, new rights not provided for such as data portability right and new data operators' obligations missing such as to notify on the data leakage.¹⁵²⁸ There has been some recent developments with the coming into force of amendment requiring some strict storage requirements on Russia's telecom and internet industries. The Russian Ministry of Digital Development, Communications and Mass Media introduced new legislative initiatives to adopt big data legislations in Russia.

In 2018, the draft Personal Data Protection Bill, 2018 (PDPB)¹⁵²⁹ was submitted to the Government of India. The draft follows the GDPR to a great extent.¹⁵³⁰ The bill includes extraterritoriality provision similar to the GDPR.¹⁵³¹ It also includes principles right such as right to access and correction, portability, right to be forgotten.¹⁵³² The PDPB includes the right to data portability where every Indian citizen can ask companies to share details of his/her personal data that has been generated while he/she was using a service or good. Individuals whose personal data is being used and stored by an organization will have the right to receive that data in a structured, commonly used format that can be read by technology or machines that any other organization may be.¹⁵³³

Transfers of personal data to third countries also requires an adequacy decision just like the GDPR and cross border data transfers is allowed under standard contractual clauses.¹⁵³⁴ The draft PDPB also requires companies to localize data where a copy of all personal data falling under the incidence of the bill should be stored in India by the data controller. Additional copies can be stored outside of India, however the government can choose to make it mandatory to store certain categories of data only in India.

The draft bill includes different penalties to address different provisions. The maximum penalty is either Rs 5 crore or to 2% of the global turnover of a company in the previ-

[data-regulation-in-russia_27nov18.ashx](#) .

1528 On May 26, 2017, the lower chamber of Russian parliament approved a series of amendments to the Russian Data Protection Act. These amendments include a new legal obligation on data controllers to report massive data leaks to the Roskomnadzor.

1529 Draft of the Personal Data Protection Bill, 2018 https://www.meity.gov.in/writereaddata/files/Personal_Data_Protection_Bill,2018.pdf .

1530 However "critical personal data" is not defined yet.

1531 Section 2.

1532 The draft bill makes reference to three categories of data: personal data that refers to any data about or relating to a natural person (named data principal in the bill); sensitive personal data which includes health and genetic data, biometrics, caste or tribe data, passwords etc. and critical personal data which remains undefined but can be notified by the central government. T

1533 Section 26.

1534 Section 41.

ous year (whichever is higher). For more severe violations, such as non-compliance with cross-border transfer provisions or consent, penalties extend to Rs 15 crore or 4% of the global turnover in the previous financial year (whichever is higher).¹⁵³⁵

There is no official right for data portability under the **Chinese** law or regulations. However, the right is mentioned in the *Information Security Technology – Personal Information Security Specification* published by the National Information Security Standardization Technical Committee, which took effect in 1 May 2018. It does not bind the administrative authorities and courts, but they can and are expected to refer to the Specification in the reasoning.

As stated in the Specification, data subjects have the right to have personal data ported to a third party if technically feasible. But this applies only to (i) basic personal data and personal identity information, (ii) health and physiological information, and (iii) education and employment information. The Specification also sets a time limit of 30 days for a request for data portability.

In principle, data controllers should not charge reasonable fees for such request but they are allowed to charge certain fees in the case of repeated requests during a certain period of time. They should also provide other plausible alternatives when facing difficulty in data porting, in order to protect the legitimate rights of data subjects. In addition, data controllers can refuse the request in consideration of public interests.

In South Africa, the Protection of Personal Information Act no. 4 of 2013 (POPI) was signed into law in November 2013 nonetheless many substantive provisions of the law have not yet come into effect.¹⁵³⁶ While not fully in effect, POPIA is generally regarded as being a codification of the current common law position in South Africa. Once POPI is in effect, it will specifically regulate the processing of personal information that is entered into a record pertaining to natural living persons as well as existing legal persons. The POPI provides users with the following rights:

- to be informed about how their personal data will be used,
- to know whether personal data is held by a data collector and to request access to their data,
- to have their personal data rectified or erased, specifying that data controllers must respond to such a request within a month,
- to restrict data processing on request from the data owner, and
- data owners must opt-in to direct marketing programmes.

The right to data portability however is not explicitly provided for in POPI.¹⁵³⁷ Arguably, the new regulator may pursue the adoption of the right in the future following suit of

1535 Chapter XI.

1536 The Act is expected to come into effect in 2019 and firms will be given 1 year to become complaint after it comes into effect. Available at <http://www.justice.gov.za/inforeg/docs/InfoRegSA-POPIA-act2013-004.pdf>.

1537 D. Eloff, *Unscrambling the General Data Protection Regulation*. De Rebus (2018). Available [here](#).

data portability principals adopted in the telecom sector.¹⁵³⁸

Cross-boarder data transfer is possible under the POPI provided the country where the information will be processed or the recipient of the information are governed by rules (whether by law or contract) similar to that of the POPI.

The POPI will be enforced by the Information Regulator. The Information Regulator has been appointed and has published the Regulations to POPI.¹⁵³⁹ Similar to the GDPR, the POPI provides for the appointment of Data protection officer which should be registered at the Information Regulator

Violation of the POPI is subject to a fine of R10 million or imprisonment (or both) for a period of no longer than ten years (section 107), or alternatively to an administrative fine (section 109).

Conclusion: With the adoption of the GDPR and its extraterritorial reach, the threshold for protecting personal data has been set to a higher standard. Among the rights conferred under the GDPR is data portability where digital users to move, copy and / or transfer their personal data across different platforms. Our discussion shows that there is still however room to develop national data protection, and data portability regulations in the US and in BRICS Countries. Except for some sectoral and state legislations, the US lags behind the EU in this regard. In Brazil, India and China, data portability is either adopted in the legislation, provided for under draft law or stipulated under relevant standards. While in Russia and South Africa their respective laws do not provide for said right.

Although it is not mainly designed as a tool to combat monopolies and market power, data portability will have significant impact on competition in digital markets. Multi-sided digital platforms are characterized by high network and lock-in effects. In a winner takes all, or most, where undertakings compete for the market rather than in the market, the right to data portability may provide some relief from the power that large digital platforms hold. It is important to note that this right only covers personal data while lock-in effects may not be just limited to personal data. It is also important to keep in mind however that data portability works both ways. For this reason, some have argued that data portability will also be imposed on small and new competitors and potential competitors as well which may result in future competing firms designing their products into a compatible format to the incumbent thus stifling innovation.¹⁵⁴⁰

Data portability is an important addition to data protection laws and with the extraterritoriality of the GDPR it is becoming a standard norm. BRICS countries that have yet to adopt the said right and those who already have should consider its impact on competition enforcement and understand its possible benefit and limitations to address market power in markets dependent on commercialization of personal data (see Table 5.1.).

1538 Telecom sector mobile number portability was introduced in 2006.

5.4.2.6. Data commons or data clubs and interoperability¹⁵⁴¹

The constitution of data commons may of course facilitate the development of new entry in data-related markets and should be promoted, for instance by enabling the diffusion of data harvested by government bodies, as this has been the case in the EU with the Public Sector Information (PSI) Directive¹⁵⁴² and more recently of the new Open Data Directive¹⁵⁴³. Another option would be to promote the development of data clubs, operating on an open, non-exclusive basis, where different companies may constitute data pools and share data, of course making sure that these are properly scrutinised and cannot serve as facilitators for cartel activity.

However, the problems arise in situations in which one undertaking holds a data bottleneck and therefore becomes a crucial node of the value chain in the diffusion of information and the realization of the productive process. This includes but does not necessarily exhaust situations of undertakings holding an essential facility. In this context, competition authorities finding a competition law infringement (e.g. abuse) may impose as a remedy interoperability. Interoperability may also be mandated by sector-specific regulators.

In this new technological environment, connectivity and interoperability constitute fundamental attributes for inclusion in economic progress: they allow individuals to access a whole new world of opportunities, economic growth and potential disenfranchisement from traditional market relationships and societal hierarchies. Conversely, the incapacity of digital objects to communicate or understand (including “mine”¹⁵⁴⁴) each other’s data thwarts the ability of consumers to contribute to the information flow with new products or services, undermining a central feature of the Internet: the significant amount of user-driven innovation unleashed by open and interconnected systems¹⁵⁴⁵. In a data-driven economy, the importance of open technical standards can hardly be overstated: common technical and legal protocols for interconnection and data processing enable communication and portability, thereby stimulating innovation and promoting competition of services within a given technological paradigm.

The degree to which such standards are truly open is likely to be a significant point of contention among different types of businesses. Granting automatic access to technol

ogy implementers can affect a technology provider's ability to appropriate the value of its innovation in downstream markets; this in turn may lead important players in the industry to not only abstain from standard-setting efforts, but also implement strategies aimed at foreclosing interoperability with competitors' technologies (horizontal interoperability) and preventing third parties from building on top of their technology (vertical interoperability). While these strategies are not new, the legal framework has so far provided solutions designed to address such concerns merely from a technological viewpoint: it has regulated the conditions under which a technology owner must grant access to the fruits of its labour. However, in doing so it has failed to articulate a clear vision on the appropriation of an important dimension of such labour, consumption data, and the web of overlapping rights that are involved in fashioning a data access regime.

Interoperability can be defined as the ability to transfer and render useful data and other information across systems, applications, or components¹⁵⁴⁶. The combination of transmission and analysis involves several layers of the so-called Open Systems Interconnection model (OSI model)¹⁵⁴⁷, requiring the achievement of various levels of interoperability¹⁵⁴⁸. At a minimum, one should distinguish the lower and the upper layer, pointing to a division between infrastructural interoperability and data interoperability. While infrastructural interoperability enables IoT devices to exchange data under common network protocols, data interoperability concerns more directly users and developers of IoT applications, allowing them to *meaningfully* connect the interfaces of those applications.

At the infrastructure (lower) layer, interoperability is achieved through the use of common protocols for the conversion, identification and logical addressing of data to be transmitted over a network. The most common standards in this layer are Ethernet and TCP/IP. Protocols are also used for communication between computer programmes over telecommunications equipment, through common languages such as HTTP for

1546 U. Gasser, "Interoperability in the Digital Ecosystem", Berkman Center Research Publication No. 2015-13 July 6, 2015. Available at SSRN: <http://ssrn.com/abstract=2639210>

1547 Open Systems Interconnection model (OSI Model) is a conceptual model that defines a unifying standard for the architecture of networking systems. For more information, see http://www.tcpipguide.com/free/t_TheOpenSystemInterconnectionOSIReferenceModel.htm

1548 More specifically, the interoperability required at the different layers concerns the following:

- At the physical layer (#1), the definition of hardware specifications; the transformation of local data into bits that can be sent over the network; and the actual transmission of those data over the network.
- At the data link layer (#2), the establishment of the functions required for the establishment and control of logical links between local devices on a network; and the procedures used by devices to control access to the network medium.
- At the network layer (#3), the logical addressing and the routing of data across a series of interconnected networks.
- At the transport layer (#4), ensuring that various software applications can all send and receive data using the same lower-layer protocol implementation.
- At the session layer (#5), ensuring the persistent logical linking of two software application processes, to allow them to exchange data over a prolonged period of time.
- At the presentation layer (#6), compressing, encrypting and translating different formats of representing data.
- At the application layer (#7), implementing the functions that are needed by users of the network and issuing the appropriate commands to make use of the services provided by the lower layers.

web content, and STMP, IMAP and POP3 for emails¹⁵⁴⁹.

At the application (upper) layer, interoperability is attained by reading and reproducing specific parts of computer programs, called interfaces, which contain the information necessary to “run” programs in a compatible format. However, different interfaces are needed depending on who actually “runs” the program¹⁵⁵⁰: if it is from the perspective of the user/consumer of the computer program, user interfaces are relevant to the extent that they enable him or her to visualize and deploy a specific set of commands or modes of interaction with the program, that can potentially be replicated into another (different) application. Importantly, although this kind of interoperability can increase a program’s utility to the user, it is not required for the purpose of its technical functioning. Most choices for user interfaces are indeed dictated not so much by functional elements of the program, as by the pursuit of the goals of user friendliness, aesthetical appeal and promotion of brand-specific features.

From the perspective of the developer of a computer program, the relevant interfaces for interoperability are the Application Programming Interfaces, i.e. any well defined interfaces which define the service that one component, module or application provides to other software elements¹⁵⁵¹. In a recent case on the scope of copyright protection for interface specifications, a US District judge distinguished three categories of information provided by these interfaces, namely (a) declaration or method header lines; (b) the method and class names; and (c) the grouping pattern of methods¹⁵⁵². In essence, these interfaces contain the information which enables third-party applications to run atop existing computer programs without a loss of functionality.

However, interoperable APIs do not necessarily imply the ability of either users or developers to meaningfully relate the outputs of interoperable computer programs, unless they are expressed in the same language (most commonly, JPEG for images, HTML for webpages, PDF for documents and MP3 for music). This can be achieved through the so called “data interfaces”, which are responsible for restoring and retrieving data in a specific format¹⁵⁵³. Differently from APIs, where specific interoperability information is required for the connection and execution of interoperable programs, data interoperability may also be obtained *ex post*, by exporting the output of the program and converting it into a readable format. This has implications for the definition of the role of regulators, as opposed to markets, should play in the promotion of systemic interoperability. Before reaching that conclusion, however, it is necessary to appreciate the extent to which legal provisions can be used to prevent, rather than achieve interoperability.

1549 See A. Van Rooijen, *The Software Interface between Copyright and Competition Law: A Legal Analysis of Interoperability in Computer Programs* (Kluwer Law, Alphen aan den Rijn 2010), p.14

1550 According to the Posix Open Systems Reference Model, these interfaces can be of four types: (a) Human/computer interface services; (b) Information interchange services; (c) Communication services; and (d) Internal system services.

1551 See C. R. B. de Souza et al, “Sometimes You Need to See Through Walls- A Field Study of Application Programming Interfaces”, in *Computer supported cooperative work*, ACM Press 2004, p. 63-71.

1552 Oracle Am., Inc. v. Google Inc., No. 3:10-cv- 3561 (N.D. Cal. June 20, 2012), ECF No. 1211

1553 See A. Van Rooijen, *supra* n. 15, *ibid*.

It is apparent that interfaces at each of these layers¹⁵⁵⁴ serve different functions, all of which are relevant for the deployment and development of, for instance, IoT applications. However, the mechanisms by which interoperability is achieved or prevented at one layer may be significantly different from those adopted elsewhere. Accordingly, it would be a mistake to think that the adoption of particular governance mechanisms to achieve interoperability at one layer implies the existence of effective interoperability across the value chain. This has particular relevance for the governance of the IoT where the magnitude of the consumer value will depend not only on the connection between objects (i.e., infrastructural interoperability), but also on their ability to read each other's data structures and concepts (semantic and syntactical interoperability), the possibility for consumers to export those data to yet other technological platforms (data portability), as well as the ability to transfer and render useful data across systems *without incurring legal liability* for accessing and processing those data (legal interoperability). Both legal and technical constraints must be taken into account for the attainment of the more comprehensive notion of "effective" interoperability.

For a computer program to be interoperable with another, the code must contain specific information, which companies might withhold from competitors, consumers and potential developers in an anticompetitive fashion. Relatedly, companies can protect that information as intellectual property, preventing third parties from relying on it for their computer programs or imposing royalties in exchange for its use. In particular, interoperability information can be protected through a patent, copyright, or a trade secret. Intellectual property (in particular, copyright and database protection) can also be used to control the use in an IoT application of data or data structures taken from another.

A third source of rights and obligations is data protection law, which determines the legal basis on which information can be extracted and re-utilized, the conditions attached to such use, and the rights of data subject to request and transfer such data. This body of law could be analyzed in parallel to sector-specific data access regimes¹⁵⁵⁵, the regulation on the free flow of non-personal data, and the regulatory framework for on open data and the re-use of public sector information. As we suggested in Chapter 4, with regard to the promotion of competition in digital markets, enhancing interoperability, and consequently promoting competition through market contestability, may be better achieved through a toolkit approach that would combine different regulatory frameworks.

One may also note an expansion of the use of the term interoperability beyond hardware, APIs and software. Some have also made suggestions as to the interoperability

1554 A mention should be made of another category of interfaces, which was briefly touched upon in the description of lower layer interoperability: the so called "communication interfaces", which connect the upper layer to the lower layer through standard languages such as the above-mentioned HTTP, SMTP, IMAP and POP3.

1555 See in this regard also I. Graef, M. Husovec & J. van den Boom, Spill-overs in data governance: the relationship between the GDPR's right to data portability and EU sector-specific data access regimes, TILEC Discussion Paper 2019-005; O. Borgogno & G. Colangelo, Data sharing and interoperability: Fostering innovation and competition through APIs, (2019) Computer and Security Law Review 105314.

of *data*, or the formats by which platforms make data available. Max Planck has issued a policy statement that interoperability of data formats and standardization very probably will increase the value of data¹⁵⁵⁶.

Issues of interoperability will certainly arise in the context of cloud computing platforms. The leading platforms (Google, Apple, Microsoft) offer vertically integrated services to their cloud computing infrastructure. Adding applications contributes to locking users into the platform.¹⁵⁵⁷ Interoperability can vary from setting harmonized cloud standards and architectures to forcing common interfaces.¹⁵⁵⁸ An important issue for competition authorities considering acting in this market is timing. Interoperability yields the greatest benefits in mature markets. Imposing it at an early stage of market development may deter investments and the incentive to innovate.¹⁵⁵⁹ While app developers might prefer ease of interoperability between platforms, the platforms force them to expend additional resources above minimal copying to integrate the service into a distinct setting. That effort costs additional resources, yet it creates additional chances to innovate that otherwise might not exist.

The burden also forces app developers to contribute to differentiating each platform. Since cloud computing is a scale service, and at least storage is a fungible service, the greater variety could enhance surplus for a subsection of clients and the platform.

Nevertheless, the platforms are seeking to increase switching costs and strengthen the lock-in effect. Existing antitrust tools can guide initial enforcement efforts, starting with market share. Entry barriers do not concern antitrust authorities until market share reaches a certain threshold. App developers still can reach consumers by complying with system terms. The primary anticompetitive effect in this context relates to higher prices that consumers may pay because of the absence of interoperability.

The timing issue implicates both market tipping and competition in innovation between platforms. A tipping point represents an unalterable junction in the competitive process: Intervening after that point both may prove fruitless and multiply costs to society in terms of sunk costs, innovation incentives, and administrative costs. A cautious approach to enforcement argues in favour of intervening sooner rather than later. Sustaining a dominant market share for more than a year or two in a network market may eliminate the opportunity for other platforms to compete. App developers may continue to write novel algorithms to evaluate information, but consumers will not gain from price competition if only one cloud service provider dominates a market. Certainly, the incentive to write that algorithm increases when several potential buyers exist. And more apps will run on a market with more than one buyer. Society benefits from more

apps testing consumer demand because actual market experiments always will determine welfare more accurately than projecting the value of a service.

5.4.2.7. Self-regulation and Codes of conduct on the basis of competition law principles

As many of the harmful effects that arise out of the restriction of intra-platform or vertical competition relate to the private governance by the platforms of their ecosystems, and before any attempt is made to regulate digital platforms, either through competition law or through some other form of regulation, it is important to explore possibilities of self-regulation, for instance through the development of codes of conduct, under the supervision of an ombudsman or of a specific specialised digital unit in the competition authority. This approach has been put forward by the recent Furman report, which mandated the digital markets unit to work with industry and stakeholders to establish a digital platform code of conduct, based on a set of core principles¹⁵⁶⁰. This code would apply to conduct by digital platforms that have been designated as having a strategic market status. Designing a code of conduct has also been proposed by the Japanese competition authorities¹⁵⁶¹.

The EU followed a 'co-regulatory approach' in the context of the Business-to-Platform Regulation¹⁵⁶². This legislation covers online platform intermediaries and general online search engines that provide their services to businesses established in the EU and that offer goods or services to consumers located in the EU. The Regulation excludes online advertising, payment services, search engine optimisation and services that connect hardware and applications that do not intermediate direct transactions between businesses and consumers, as well as intermediaries that operate between businesses only. The Regulation requires online platform intermediaries and online search engines to comply with legal obligations (including obligations of transparency and non-discrimination) and encourages them to take voluntary complementary steps. Online intermediation platforms have been put in place in order to set up an internal complaint handling system that would allow businesses to lodge complaints directly with the platform for example, as a result of an action or decision taken by them or as a result of a technological problem. The Regulation requires platforms to respond to complaints appropriately and communicate the outcome to businesses. The Regulation also provides organisations and associations representing business users' interest to take action before competent national courts to stop or prohibit non-compliance with the Regulation.

The Regulation relies on private enforcement and ADR. This is also justified by the fact that, contrary to the UK code of conduct, it applies to all platform intermediaries, the entire online platform economy in the EU with approximately 7000 online platforms

1560 Furman Report, 138, Recommended Action 1.

1562 Regulation (EU) 2019/1150 of the European Parliament and of the Council of 20 June 2019 on promoting fairness and transparency for business users of online intermediation services, (2019) OJ L 18657.

or market places operating in it –which include Big Tech, as well as very small start-ups, without any condition relating to the market power or the strategic position of the platform, although some of the Recitals of the Regulation make reference to asymmetrical bargaining power or superior bargaining power¹⁵⁶³. This shows that for the EU legislator this framework (ADR-based and in some cases private enforcement-based) is complementary to competition law enforcement, which can focus on situations in which there may be harm to consumers, the competitive process and more generally the public interest. Such combination of self-regulation or co-regulation with the enforcement of competition law in situations of horizontal or vertical power may seem a preferable option, also for BRICS countries.

5.4.2.8. Competition by design

‘Competition by Design’ constitutes a proactive approach that undertakings might take to address antitrust problems in markets where algorithms influence competition. It forces programmers to implement competition law principles into the design of algorithms.¹⁵⁶⁴ The concept derives from Article 25(1) of the EU General Data Protection Regulation (GDPR) that sets-out data protection by design.¹⁵⁶⁵ The objective motivating the idea is to prompt the best efforts of undertakings to comply with competition values without imposing a specific technological path.¹⁵⁶⁶

In the general context of law, undertakings may need to convert statutory or common law principles into simple rules quantifiable in code.¹⁵⁶⁷ Alternatively, machine learning may be able to detect patterns in legal decisions. Machine learning functions by searching the most predictive inputs to construct a path to the correct output.¹⁵⁶⁸ With algorithms gaining greater prominence in societies, antitrust authorities may need to mandate welfare maximizing objectives in different contexts, for instance, economic activity for search algorithms. Undertakings at least may institute a two-tier review process, with algorithms first screening proposed decisions.¹⁵⁶⁹ Another method of operation, relating directly to consumers, might involve displaying information about how a dominant platform complies with its special responsibility for particular functions.¹⁵⁷⁰

Competition by design has strengths and weaknesses, and thus uncertain prospects.

1563 Recitals 2 & 23 when explaining the ratio legis of the Regulation. These are not however operationalised as conditions for the application of the Regulation in specific cases.

1570 S. Vezzoso, Competition by Design, pp. 17-18 (2017), https://papers.ssrn.com/sol3/papers.cfm?abstract_id=2986440, 28.

The chief weakness consists of viability. Competition law can consist of imprecise contextual orders and standards.¹⁵⁷¹ Algorithms may not have the sophistication to determine how a decision impacts a market.¹⁵⁷² Undertakings engaging in activities that do not reduce to automation could incur penalties at a greater frequency.¹⁵⁷³ Undertakings may have different capabilities in terms of hardware to execute the coded precepts of competition law, creating entry barriers. The obligation will add to marginal costs and inhibit the technology from spreading.¹⁵⁷⁴ Competition by design may, on the other hand, enable competition authorities to condemn anticompetitive conduct, the leading example being tacit collusion, previously out of reach.¹⁵⁷⁵

Regulation Technology (Reg Tech) may enhance competition by design. It features software following regulatory information across jurisdictions that attempts to measure the impact regulatory changes may have on a company, including the risk to profitability. Reg Tech notifies the responsible parties within organizations, and recommends state of the art responses.¹⁵⁷⁶ One may imagine the possibility of developing RegTech as an instrument of enhancing compliance, by automating the process of competition law screening of algorithms, smart contracts and possible other code-able business conduct through RegTech algorithms and machine learning tools developed by competition authorities, either internally or in cooperation with external partners (e.g. Universities, companies). Such initiatives may be first tried through pilot projects and then generalised in specific areas of competition law enforcement involving in particular types of conduct for which the current state of AI may handle with relative accuracy. Although the process cannot be automated 100%, and would still need some human input, it could augment the current capabilities of competition authorities and may also enable a better (more accurate) filtering of possible anticompetitive conduct to be examined more thoroughly by dedicated teams at a later stage.

5.5. Enforcement statistics – digital antitrust in BRICS countries

We have collected and coded 236 merger cases and 109 antitrust infringement cases dealing with the digital economy across the five BRICS jurisdictions over the period 2008-2019. We have coded 28 merger cases from South Africa, 2 merger cases from

Russia, 9 merger cases from India, 5 merger cases from China, 188 merger cases from Brazil. We have coded 5 infringement cases from South Africa, 10 infringement cases from Russia, 45 infringement cases from India, 32 infringement cases from China, and 17 infringement cases from Brazil.

5.5.1. Aggregate BRICS

The statistical patterns illustrated here provide insight into the enforcement priorities so far of the BRICS competition authorities.

5.5.1.1. Aggregate BRICS mergers

Figure 5.1: Distribution of supply chain types – BRICS aggregate mergers

Figure 5.1. illustrates the distribution of supply chain types in all merger cases concerning the digital markets in the BRICS countries. Most merger cases concerned the data processing, followed by data sharing, data generation and data commercialization, and lastly data storage.

Figure 5.2.: Distribution of products – BRICS aggregate mergers

In figure 5.2., the merger cases in the BRICS countries concerning digital markets are classified according to the sector involved. By far the greatest number of mergers involved the telecommunications sector, followed by computer programming. Otherwise, merger activity was distributed widely among sectors, with no other single sector breaking 10 per cent of total mergers.

5.5.1.2. Aggregate BRICS infringements

Figure 5.3.: Distribution of supply chain types – BRICS aggregate infringements

Figure 5.3. describes the distribution of infringement cases (antitrust) concerning the digital markets in all BRICS countries combined according to the level of the supply chain involved, with firms involved in data generation responsible for the most infringements, followed by data sharing, data commercialization, data sharing, data communication and lastly, data storage.

Figure 5.4.: distribution of sectors – BRICS aggregate infringements

Figure 5.4. describes the aggregate BRICS infringement cases categorised according to sector. Similar to the trends seen in mergers, the largest sectors are computer programming and telecommunications (wired and wireless).

Figure 5.5.: distribution of infringement types by sector – BRICS aggregate infringements

Figure 5.5. describes the various infringement types for each sector in the aggregate BRICS food sector infringement cases. While there is substantial variety among sectors, abuse of a dominant position cases are prevalent in most of the product categories, with cartels also present in a notable minority of instances. The more atypical infringement types (e.g. business defamation) stem from the Chinese jurisdiction.

Figure 5.6.: proceedings by infringement type – BRICS aggregate

Figure 5.6. notes the infringement proceedings in the BRICS countries according to the type of infringement. Reflecting figure 5.5., the primary reason for starting infringement proceedings has been abuse of a dominant position.

**Figure 5.7.: distribution of reasons for proceeding by infringement types – BRICS aggregate**

Figure 5.7. provides a distribution of the reasons for starting infringement proceedings in the BRICS countries for each infringement type. For all types of infringements, complaints have been the most prevalent reason for starting the procedure. Cartel proceedings have also been instigated by means of sector inquiry and leniency. Likewise, abuse of dominance proceedings have been instigated by sector inquiries and ex officio.

In the following sub-sections, we replicate the figures displayed above for each of the five BRICS jurisdictions.

5.5.2. Brazil

Chapter 6: E-commerce, competition law and digital vertical restraints

Ioannis Lianos, Nicolo Zingales with Azza Raslan, Matt Strader and the BRICS teams

6.1. General discussion

Rapid developments in the e-commerce markets have revolutionised distribution practices. The significance of such developments is particularly visible in BRICS economies: in 2015, China and Russia's ecommerce registered growth rates of 27% and 25%, each respectively, while Brazil and South Africa were both in the 15% range¹⁵⁷⁷. India topped the growth chart for the BRICS economies for the same period with an annual e-commerce growth rate of 54%. In any case, all BRICS economies were above the world average which was at an annual growth rate of more than 12% for the same period.¹⁵⁷⁸ These numbers have already significantly increased and are expected to increase further especially in India, China and Brazil, as a large percentage of new Internet users are projected to come from these countries¹⁵⁷⁹. While India's online retail market is the fastest growing amongst BRICS and even worldwide, having witnessed a compound annual growth rate (CAGR) of 53 per cent for the period 2013 to 2017.¹⁵⁸⁰

Box 1 E-commerce in BRICS Economies: A Rising Trend

The Indian e-commerce sector has grown exponentially from US\$14 billion in 2014 to US\$39 billion in 2017, and is expected to reach US\$200 billion in 2026¹⁵⁸¹. This is in line with estimates of a burgeoning increase of India's total internet user base,

1577 United Nations Industrial Development Organization and Shanghai Academy for Social Sciences, 'Ecommerce Development Report for Small and Medium-Sized Enterprises in BRICS Countries', < https://www.unido.org/sites/default/files/files/2018-07/E-commerce%20Development%20Report%20%28SASS%29_09072018.pdf>; see also 'Status, Opportunities and Challenges of BRICS E-commerce' (Report prepared by UNIDO and ITC) <[http://www.intracen.org/uploadedFiles/intracenorg/Content/Publications/BRICS%20E-commerce%20_Status%20Opportunities%20and%20Challenges_22AUG2017_final\(1\).pdf](http://www.intracen.org/uploadedFiles/intracenorg/Content/Publications/BRICS%20E-commerce%20_Status%20Opportunities%20and%20Challenges_22AUG2017_final(1).pdf)>

1578 India registered a spike of 180% growth in 2015, but however followed by a mere 12% in 2016. See 'E-commerce in India: From 180% in 2015, growth crashes to 12% in 2016 at \$14.5 bn', <https://www.financialexpress.com/industry/e-commerce-in-india-from-180-in-2015-growth-crashes-to-12-in-2016-at-14-5-bn/530070/>

1579 'Digital 2019: Global Digital Overview', at <https://datareportal.com/reports/digital-2019-global-digital-overview->. See in particular "Internet Growth Ranking" (placing these three countries in the top 10, with India and China in the top 2)

1580 Bain & Company Report. By comparison, China has a CAGR of 33 per cent over the same period. 'India is fastest growing e-commerce market: Report' The Times of India (29 November 2018) <<https://timesofindia.indiatimes.com/business/india-business/india-is-fastest-growing-e-commerce-market-report/articleshow/66857926.cms>>.

1581 *ibid.*

specifically from 560.01 million in September 2018. to 829 million by 2021¹⁵⁸². Considering the giant leaps in Internet penetration, it has also been noted that the next 100 million e-commerce customers will be of a very different demographic from the existing 50 million (for instance in term of age, knowledge of English, urban location, etc), which might require the adoption of different policies and strategies.¹⁵⁸³

China is another key player in global ecommerce. According to a 2017 Report by the United Nation Industrial Development Organization and the Shanghai Academy of Social Science, total e-commerce transaction volume had an average annual growth of 35%, accounting for 65% of China's GDP¹⁵⁸⁴. More recent estimates by eMarketer reveal that China's ecommerce sales in 2019 are expected to grow much faster than its total retail, increasing 27.3% year over year to \$1.935 trillion¹⁵⁸⁵. By 2023, its retail ecommerce sales will represent 63.9% of total retail sales¹⁵⁸⁶. Against this backdrop, it is interesting to note that there has been so far no anti-trust enforcement in this area, despite the existence of a legal prohibition specifically addressing certain types of vertical agreements¹⁵⁸⁷.

Brazil registered 27.4 million active consumers of e-commerce during the first semester of 2018, which represents a 7.6% growth when compared to the same period of 2017. Brazilian individuals spend 433 BRL (roughly 115 USD according to the exchange rate of February 2019) on average for each e-commerce transaction. According to the IBGE survey (TIC Domicílios), in 2017, 35% of Brazilian internet users had engaged in e-commerce, acquiring products or contracting services through the internet in the last 12 months¹⁵⁸⁸. The 38th Edition of the Webshoppers Report¹⁵⁸⁹, conducted by Ebit/Nielsen, shows that 68% of the e-commerce transactions happen through PCs, and 32% via mobile devices. The sales by mobile devices grew by 30% in 2018 when compared to 2017, totalling 17.4 million transactions, a trend consistent with the increasing importance of mobile access to the internet. However, data also suggest that consumers still use comparatively more PC access for e-commerce (68% of transactions for 56% of PC access versus 32% of transactions for 97% of mobile access).

South Africa has been growing at a constant rate, despite forecasts initially predicting a slowdown. In 2015, when the scale of e-commerce was quite small in the country, the rate of growth of online retail was 26%, and 60.8% of the Internet user base were ready to shop online¹⁵⁹⁰. In the following years this was expected to decrease to 20%, but the numbers remained stable around 25%¹⁵⁹¹, up to last year¹⁵⁹². The 2019 e-Commerce Report from World Wide Worx reported in November 2018 that total revenue from e-commerce sales in South Africa would reach R14 billion by the end of the year. According to market research company Statista South Africa will have as many as 21,5-million online shoppers in 2019, that's almost 40% of the population. However, online retailers still make a relatively small proportion of the overall retail¹⁵⁹³. There is still a large margin for improvement also on the expansion of the user base, given the forecast that Internet penetration will rise to 80.8% in 2023, from 59.8% in 2017¹⁵⁹⁴.

The Russian e-commerce sector has also been growing rapidly. In 2018, the Russian e-commerce market was estimated to amount to 1 trillion roubles (approximately 13,5 billion EUR) with 18% annual growth, and the share of e-commerce in retail non-food sales reached 7.2%.¹⁵⁹⁵

With an increasing number of smartphone users, online retail has provided substantial opportunities for product/service providers to develop innovative business models to efficiently expand their market boundaries. E-commerce has also revolutionised the consumer experience – expanding the choice of suppliers, ability to compare prices and quality of products/services. These opportunities have resulted in traditional brick-and-mortar stores experiencing different perspectives of competition in online retail – from designing distribution networks, to pricing on platform markets, to opportunities of advertisement. This is particularly relevant for the BRICS economies where B2C is particularly growing at a fast pace. Despite some fluctuation over the past three years, more recent data shows BRICS economies among the top ten developing and transition economies in their respective regions in B2C e-commerce in 2018.¹⁵⁹⁶

6.1.1. The growth of e-commerce and digital vertical supply management

The growth of the Internet and the subsequent development of electronic business has profoundly transformed the distribution segment of supply chains as well as the relations between the various segments of the chain. The rise of electronic commerce has been an important feature of economic development globally since the mid-1990s. Early Electronic Data Interchanges (EDI) between trading partners were first incorporated in Business to Business (B2B) transactions, before Internet technologies were applied to Business to Consumer (B2C) exchanges that took off in the second wave of electronic commerce from mid-2000s. The expansion of the more rapid broadband connections, until then merely used by business, to consumers, which were until then connected to the Internet using much slower dial-up modems, has contributed to this development. The increased use of the Internet, the more intensive use of e-mail technologies, the growth of online advertising activity and subsequently the development of Web 2.0 technologies, allowing users to participate in the creation, editing and distribution of content online, were among the factors explaining the phenomenal increase of the economic significance of electronic commerce globally.

The third wave of electronic commerce has led to important changes in business practices and will certainly disrupt existing business models of distribution of products (including services). The widespread use of smartphones (mobile phones including an operating system enabling the users to run various software packages and a Web browser), or the development of tablet computers have led to the emergence of mobile telephone based commerce (or m-commerce), thus further increasing the opportunities for growth of e-commerce. Social networking technologies enable social platforms, such as Facebook, or microblogging platforms, such as Twitter, to emerge as additional e-and m-commerce sites, taking advantage of interpersonal connections to provide targeted advertising or promotion of products (social commerce). Big Data analytics and the massive collection of personal data may further help in tracking with detail the behaviour of consumers (their digital identity), when navigating the Internet, and help companies predict the kinds of products and services consumers may be interested in. These tracking technologies, such as barcodes, bokodes, smart cards and Radio Frequency Identification devices are embedded in the various objects, collecting data about them without

any human intervention and feeding this information into computer systems, thus enabling supply chains to monitor where their products are at all times. Major global companies, including distributors such as Wal-Mart and branded goods suppliers, such as Gillette, Procter & Gamble, Coca-Cola, Unilever, Johnson & Johnson are supporting the Auto-ID Labs, research entities working on the integration of tracking and communication technologies into B2B exchanges and on the architecture of the Internet of Things, which will significantly affect the way supply chains operate by, for instance, enabling higher in-transit visibility and significantly cutting down logistics.

Technological changes have played an important role in the revision of the EU rules on distribution agreements in mid-1990s, arguably as important as the change of policy paradigm with the advent of the 'more economic approach' and the increasing influence of economics in determining the scope of intervention of competition authorities concerning 'vertical' restraints.¹⁵⁹⁷ The attributes of these technological changes could be summarized as follows:

First, they significantly decrease organisation and monitoring costs, improving the level of communication between the various business units of a vertically integrated firm, while at the same time they decrease transaction costs at the marketplace, for instance by considerably limiting search costs. This may affect the incentives of firms for vertical integration and also leads to the development of network economic structures, where independent economic entities form long-term relationships with other companies, sharing resources and jointly developing strategies. These networks may take different forms: strategic alliances and partnerships, supply webs interconnecting various strategic alliances and complex outsourcing contracts, electronic marketplaces and portals. These networks form industry value chains, sometimes long, sometimes short, always oriented towards the final consumer and enclosing a series of primary (identify customers, design, purchase inputs, manufacture, market and sell, deliver, provide after-sales services and support) and supportive activities (finance and administration, human resources, technology development activities).

Second, the possibilities offered by tracking technology and the wider availability of personal data, on the online and market behaviour of consumers, have led a number of companies to develop, more effectively, commercial practices that discriminate between different market segments, divided according to the customers' characteristics (gender, age, geographic location, income level, personality, approach to life etc), leading to different forms of market segmentation. This is particularly important for focused advertising and e-marketing, eventually also pricing the products or offering specific tailored-made to these segments, versions of them. This may of course enable these firms to extract more revenue out of the various market segments, if they are able to

1597 Already at the Green Paper on Vertical Restraints in EC Competition Law (1997), available at http://ec.europa.eu/competition/antitrust/others/96721en_en.pdf paras 40–43, the Commission noted that the '[w]hole nature of distribution has been changed by the Information Technology Revolution', citing Just in Time principles in the organisation of manufacturing and distribution, quick response logistics, Electronic Data Interchange, bar coding, laser scanners as important innovations 'involving a shift from the traditional arms-length relationship between manufacturers, wholesalers and retailers towards a relationship of co-operation particularly in the area of logistics'.

prevent arbitrage between the different groups of customers. This market segmentation may be achieved either unilaterally or with the cooperation of the other parts of the supply chain, through specific agreements ensuring the effectiveness of the segmentation, which could eventually give rise to different forms of vertical restraints.

Third, through technology supply chain management becomes a more effective and less expensive, enabling companies to achieve higher quality at a lower production cost. Firms find it crucial to enter into long-term agreements with partners in other segments of the chain, in order to create the necessary relation of trust that is required by the importance of relation-specific investments that need to be undertaken in setting the supply chain management. This may lead to disintermediation and vertical integration but also to deconcentration through the constitution of networks or supply alliances that are managed by supply chain councils. These various forms of supply chain management share the common characteristic that they are all ultimate consumer orientated, as any segment of the chain directs its efforts towards meeting the needs of the next member of the chain, the perception being that all segments of the chain do not constitute separate islands of activity but essential ingredients for the formation of the total value of the chain. For instance, brand-building takes the wider perspective, that of the whole value chain, leading to the elaboration of labels and standards to which the various segments of the chain abide. Issues relating to the distribution of the total surplus value of the chain also take a prominent role in the relation between the various economic actors participating to the supply chain, in particular as supply chain management, even if it is flexible, crystallizes more easily their position (and share). Alternatively, the possibilities offered by private electronic marketplaces and portals, such as Amazon. Supply which also operates as an actual distributor, with warehouses and products stocked on shelves, may lead firms to opt for a spot-market method of organisation of their economic activity, if the nature of their products and other considerations does not justify the cost of elaborating long-term supply relationships.

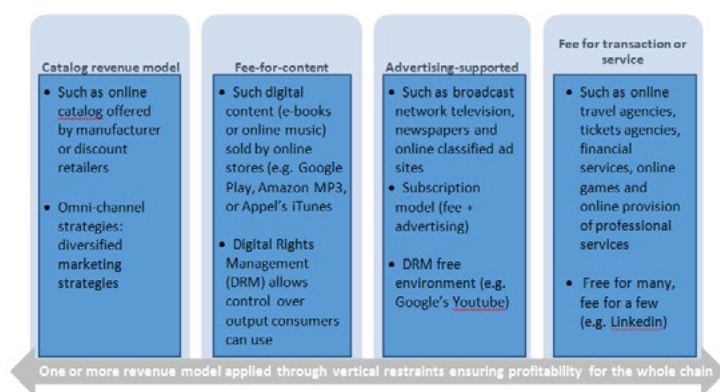

Fourth, Internet and the advent of digital economy profoundly changes the organisation and the revenue models of the industry. Long gone are the days where distribution was organised as a web of conflicting interests, each of the actors (manufacturer, wholesaler and retailer) acting in order to defend their interests and develop independent strategies, sometimes to the detriment of the chain. Online commerce enables manufacturers to bypass intermediaries by proceeding to a direct distribution of their product through the Internet. This can take the form of the conventional catalog revenue model, with the difference that the catalog is now online, consumers placing orders through the manufacturer's website. Internet also empowers discount retailers to lower down their costs and thus to take advantage of the fact that their website operates as a hub for discount offers from different manufacturers. Marketing channels are also diversified, with the development of omni-channel strategies, where manufacturers operate their own website, while also distributing through traditional retailers, online retailers and discounters.

The distribution of digital content may also rely on the fee-for-content revenue model. An example is e-books or online music, which are sold as digital content by online stores, such as Google Play, Amazon MP3, or Appel's iTunes. Digital Rights Management software empowers the sellers to limit the number of copies of the audio file that consumers can use, although there are also companies opting for a DRM-free environment, relying on a different revenue model (Google's Youtube, the leading source of free videos on the Web relies on an advertising revenue model).

Advertising-supported revenue models have been on the rise. This is a well-tested model for the distribution of content, for instance used by broadcast network television, newspapers and online classified ad sites. Sometimes it is combined with a subscription model where consumers pay a fee but also accept some level of advertising. These business models usually rely on multi-sided platform strategies, bringing together two or more interdependent groups of consumers, information technology and the possibilities offered by Big Data technology and the social Web to collect personal data making it an extremely valuable business method for advertisers. This provides incentives to the various economic actors to strategically design platforms that appeal to multiple sides, thus increasing the instances of platform competition.

Fee for transaction or fee-for service revenue models have been increasingly used by online travel agencies, tickets agencies, financial services, online games and for the on-line provision of professional services. Sometimes, these models rely on a free for many, fee for a few revenue model where companies try to attract consumers by providing a number of digital products for free, while enticing a small number of consumers to buy a more sophisticated and relatively expensive version of the product (e.g. LinkedIn).

Figure 6.2. Impact of Technological Effects on Revenue Models

Source: Author's illustration

These various models may co-exist in the same industry but also within the same supply chain. They are often implemented through vertical restraints, which aim to ensure the profitability of the whole supply chain, as opposed to the profitability of just the specific segment of the chain, by institutionalising procedures for the distribution of profit margins along the chain. This alters the usual understanding that each economic transaction should be assessed at the level of the chain it intervenes, without any consideration to other sides of the platform or other segments of the value chain. Competition

authorities ought to be careful not to influence the choice of the most effective revenue strategy for undertakings and keep a position of neutrality with regard to the revenue models chosen. However, they cannot assume that the conflicting web of interests will lead the various levels of the chain to police each other (the so called self-policing character of vertical restraints) which have led many competition authorities to abandon the area of vertical restraints in setting their enforcement priorities, deciding instead to focus on cartels. These important economic and technological transformations and the increasing importance of supply chain management may call for new operational concepts in competition law and the development of a more ‘holistic’ approach that engages more fully with value chains.

6.1.2. How do changes in technology affect the types of vertical restraints adopted?

Given the above-sketched transformation in the dynamics of distribution and monetization, it is logical to expect vertical restraints of a somewhat different nature in the digital environment. At the very least, the strategic role of individual-level data generated through consumer-facing entities, such as e-commerce platforms and online aggregators, will encourage specific types of restrictions (technical and contractual) in the ability of suppliers to use those insights outside their native environment. Further, the effects of these restrictions may be strengthened by exclusivity requirements on the sourcing of ads¹⁵⁹⁸, which often constitutes a crucial monetization strategy. At the same time, due to the vast array of available data points suppliers can now be put by online platforms in a much more effective position to not only adjust their offer to the needs of demand, but also to anticipate and even create demand for consumer groups who are the target of sophisticated profiling. In other words, the “prediction products” that can be traded on the basis of behavioral data¹⁵⁹⁹ have become a key competitive asset that can be leveraged to increase sales. This may lead to differences in pricing and in content depending on key consumer characteristics, such as affluence, behavioral preferences, and even time of purchase (through not just “yield” but also “dynamic” pricing).¹⁶⁰⁰ A further advantage of this model is that it allows sellers to reach more quickly a broader

1598 An example of such restrictions is the recent decision adopted by the European Commission with regards to Google’s contractual prohibition for publishers of ads served through its AdSense to host ads from competing services. See https://europa.eu/rapid/press-release_IP-19-1770_en.htm

1599 The term is used by Shoshana Zuboff, *The Age of Surveillance Capitalism: The Fight for a Human Future at the New Frontier of Power* (Public Affairs, 2019).

1600 In the context of online hotel reservations, for instance, it was reported that Mac users received higher quotations than PC users. See Dana Mattioli, ‘On Orbitz, Mac Users Steered to Pricier Hotels’ (WSJ, 23 August 2012), <<https://www.wsj.com/articles/SB10001424052702304458604577488822667325882>> accessed 10 July 2018. Similarly, a study where researchers created fake online accounts to survey pricing of 600 different products from 200 vendors found that products up to 4 times more expensive were shown to affluent personas rather than the budget conscious personas. Jakub Mikians, László Gyarmati, Vijay Erramilli, Nikolaos Laoutaris, ‘Detecting price and search discrimination on the Internet’, *Proceedings of the 11th ACM Workshop on Hot Topics in Networks*, 79-84. See also <https://www.theverge.com/2012/12/24/3800472/retailers-adjusting-online-prices-depending-on-income-and-location>.

audience, thanks to each platform's infrastructure, and to benefit from the platform's established reputation.

It is important to appreciate that reliance on third party platforms is but one of the options available to enter the market: sellers may for instance prefer to develop their own online distribution channels. The incentives and strategy are different from the previous scenario, as they require more investment in advertising to create brand awareness, and to build reputation and trust. In this context, the conventional wisdom is that restrictions preventing free-riding over that advertising are necessary; and that it is legitimate to enforce strict conditions for selective distribution systems when they are necessary, based on criteria that are determined and applied objectively, and do not go beyond what is necessary¹⁶⁰¹. However, it has been noted that the rationale of protecting the aura of reputation around a particular brand which leads to the brand owner's ability to charge high prices may have been too readily accepted in the past by courts and competition authorities, particularly where consumers' willingness to pay is not based on informed choices but largely driven by behavioural biases and other market failures¹⁶⁰². Accordingly, it may be sensible to scrutinize more closely vertical agreements in order to foster intra-brand competition as a de-biasing measure that allows different retailers to convey to consumers more information about the real value of any product or service in question¹⁶⁰³.

Another alternative strategy for producers to reach consumers is via a combination of their online distribution channel with offline retail (so called "bricks-and clicks" or "mix play" strategy). In this case, the two channels can be used effectively to subsidize each other, taking advantage of the wide circulation of information online to develop brand awareness and use the existing physical infrastructure to fulfil demand. In this context, the challenge for producers is one of avoiding cannibalization- that is, ensuring continuous feedback loop between the channel and preventing online to replace offline sales, rather than supplement them. For this reason, a requirement for distributors to have a brick and mortar shop may be a sensible criterion in a selective distribution system, provided it fulfils the above-mentioned conditions- and in particular it is justified by the nature of the product. With the advances of digitalization, the basis of this determination is likely to become more empirical thanks to the existence of large amount of consumption data, indicating for instance geographical and ethnical preferences: more accurately identifying the target population can lead to more effective stocking of stores, further enhanced by automated replenishment. This illustrates that the predictive power of Big Data can be effectively used even without using third party platforms and targeting consumers to the individual level, as it can lead to more efficient planning and decision-making. Amazon has recently taken this to the next level by filing a patent for "anticipatory shipping", which cuts the intermediary step of the local store and ship

1601 Guidelines on Vertical Restraints, para. 175.

1603 Id., 100.

to Amazon warehouses the products that consumers in a particular geographical area are likely to order¹⁶⁰⁴.

6.1.3. What are the recent changes in business methods observed?

The development of e-commerce is very much linked to superior processes of supply-chain management and Just in Time inventory management, facilitated by Big Data, augmented reality, the use of analytics and deep learning to customize the shopping experience drones, advanced robotics and algorithms. The development of logistics near metropolitan centres forms part of the required fixed costs for the establishment of an e-commerce platform, in particular as competition with regard to the cost and time of the delivery becomes more intense. Amazon has set new standards delivering products ordered online within 48 hours, and in some cases 24 hours with the use of autonomous robots¹⁶⁰⁵. The company has become a logistics behemoth, competing with multinational courier delivery services, such as Fedex and UPS, although it is at the same time their customer (frenemies)¹⁶⁰⁶. The complexity of the competitive game and the hybrid horizontal and vertical character of the relations call for a careful than what is usually afforded to pure vertical restraints. Beyond the issues raised by the eventual dominance of an e-commerce platform, in particular those related to its dual role as platform and merchant, various contractual interactions between the e-commerce platform and the merchants may fall under the competition laws on collusive practices. This is not the first time where we observe a blurring of the horizontal/vertical distinction and the emergence of hybrid restraints. Of particular interest for this purpose is the practices of category management and private labels, which have attracted the attention of competition authorities in the past. Category management is a vertical partnership in which previously confidential information is shared between manufacturers and retailers in order to cut costs in distribution and increase the margin of both parties. The major impetus for this type of arrangement came from the supermarket industry as a response to the intense competition of warehouses and discounts stores. The category captain presents a plan-o-gram to the retailer suggesting a layout and a promotional plan for the entire category.

There are different forms of category management arrangements, going from strong ones, when the category captain has joint responsibility with the retailer for category development and is entrusted all category decisions, to loose forms of category management, where the retailer also received second opinions and recommendations from other category captains or the role of the category captain is an advisory one¹⁶⁰⁷. Ac-

1605 See <https://www.washingtonpost.com/gdpr-consent/?destination=%2ftechnology%2f2019%2f08%2f12%2famazons-autonomous-robots-have-started-delivering-packages-new-location-southern-california%2f%3f>

1606 See, <https://multichannelmerchant.com/operations/fedex-cites-amazon-competition-first-time-10k/>.

1607 D M Desrochers, G T Gundlach and A A Foer, 'Analysis of Antitrust Challenges to Category Captain Arrangements' (2003) 22 Journal of Public Policy & Marketing 201, 204.

According to the EU Vertical Restraints Guidelines, category management may ‘sometimes distort competition between suppliers, and finally result in anticompetitive foreclosure of other suppliers, where the category captain is able, due to its influence over the marketing decisions of the distributor, to limit or disadvantage the distribution of products of competing suppliers’.¹⁶⁰⁸ This comes essentially from the conflict of interest between the supplier and the retailers, although the Commission notes that ‘in most cases the distributor may not have an interest in limiting its choice of products’.¹⁶⁰⁹ Category management might, however, produce exclusionary effects to other suppliers, in particular when the category captain is able, due to its influence over the marketing decisions of the distributor, to limit or disadvantage the distribution of products of competing suppliers.

Furthermore, new commercial practices, such as drop shipping, open book costing or yield pricing, may require from competition authorities an effort to adapt their conceptual toolkit. Drop shipping involves the selling a product without the responsibility of carrying inventory or shipping the goods, dropshippers setting their own product prices. The practice reduces the commercial risks for the e-commerce platform which is thus able to reduce its costs and capture the highest part of the surplus value, by imposing additional conditions in order to authorise drop shipping on the platform. For instance, Amazon allows dropshippers to sell on its platform but they can only dropship via Amazon’s Fulfillment by Amazon (FBA) services. This configuration raises interesting questions as to the characterization of the relation between the platform and the manufacturers as a genuine commercial agency, therefore benefitting from some immunity.

6.2. Foundations for the competition assessment of online vertical restraints

6.2.1. Are online vertical restraints different from offline vertical restraints?

One could first look to the possible pro-competitive narratives of online vertical restraints. As it is also the case for offline vertical restraints, online vertical restraints deal with externalities. These can be of various sorts and are not necessarily exacerbated in an online setting. For instance, a free-rider problem may emerge in the provision of retail services if an offline retailer cannot fully appropriate the returns from providing services, such as in-store demonstration and trained sales staff). This does not only occur with regard to competition between offline and online distributors, but also between online distributors, as low-cost platforms, or direct online sale at the manufacturer’s/supplier’s website may free-ride on rival platforms’ investments in retail services such as online reviews and advice in relation to products sold. Exclusive dealing restraints or RPM may solve this horizontal externality problem. Minimum RPM may also reduce free-riding by preventing retailers who do not provide the necessary retail services from discounting the product. However, one should be cautious in overstating the free-riding

¹⁶⁰⁸ Guidelines on Vertical Restraints [2010] OJ C 130/1, para 210.

¹⁶⁰⁹ Ibid.

argument, as the large quantities of online information may weaken the potential for free-riding and one cannot exclude the possibility that free-riding works at the opposite direction with offline retailers free riding on online retailers.

Online vertical restraints may also be found necessary if retailers that do not have an established reputation are able to free-ride on the reputation and quality certification made by other retailers. One may however oppose to this argument the fact that online sellers increasingly focus on non-price aspects of competition, by investing in reputation and developing online retail brands. Online retailers, such as eBay, Amazon, Alibaba, are among the most valuable brands in the world.¹⁶¹⁰

Furthermore, it is possible that online commerce may generate information asymmetries particularly in relation to the quality of goods and services available online and the reputation of online sellers, as consumers are not able to physically inspect a product prior to purchase and may have little information about the quality and reputation of some online sellers. However, one may object to this argument that there is enough competition between online sellers on non-price aspects, which could contribute in reducing information asymmetries for consumers, in particular as online platforms are offering consumers the opportunity to provide feedback online, once the sale is completed.

Finally, in the presence of demand uncertainties for new products, it is also difficult for entrants to find an offline retailer/distributor if online distribution is available, pushing the suppliers to adopt restraints such as the obligation to dispose of an established offline presence. This does not take account of the fact that Internet also offers suppliers the possibility to promote the product directly online or on social media and to ship the product directly to the consumer.

Online vertical restraints may also give rise to anti-competitive effects. These can be of various sorts. They may foreclose downstream rivals (retail foreclosure) if the supplier introduces limitations to online sales and imposes dual pricing, which reduce online retailers' access to the products, thus raising prices and restricting consumer choice, in particular if the product is a 'must have' product. Through exclusive distribution agreements with key distributors, the supplier may foreclose his rivals that can only use less efficient distribution networks or incur the expenses for setting up their own. This is less of a concern in situations of disintermediation, in which the supplier relies less on traditional distributors and deals directly with consumers. Online vertical restrictions, such as parity clauses (Across Platform Parity Agreements – APPAs) may protect platforms from disintermediation, while selective distribution or exclusive dealing clauses may hinder the development of new distribution platforms.

Consistent with the dampening competition theories of harm for offline commerce, online RPM clauses may soften competition between retailers and between suppliers. An APPA may also restrict a supplier's ability to charge lower retail prices on a lower-fee platform and thus increase its sales. Online RPM make prices more transparent, by of-

1610

fering a focal point for retailers to increase their ability to coordinate higher retail prices, thus facilitating upstream collusion. APPAs may also facilitate collusion between platforms by reducing a platform's incentives to deviate from a collusive arrangement, for instance by offering lower fees to sellers on the platform. Cumulative network effects may also arise more frequently in online markets given the greater scope for expansion of geographic sales and disintermediation. This may be exacerbated by the relatively higher concentration of online commerce, as entry costs in online retailing are most often sunk costs and there are important network effects, the first mover enjoying a fairly important competitive advantage compared to its rivals, thus leading to the easier emergence of a situation of single-firm dominance.

6.2.2. Platform governance and commercial agency immunity

Given the variety of match-making and distribution models adopted by online platforms, it is crucial for antitrust analysis to examine the specific characteristics of the relationships between those platforms and their featured sellers or suppliers. This is critical not only in order to appreciate the effects of the arrangements in place between actors operating at different level of the value chain, but also to determine whether such arrangements could be subject to antitrust scrutiny altogether. Platform governance choices may indeed fall outside the scope of antitrust analysis as a result of the application of the "single entity" or "single economic unit" doctrine¹⁶¹¹, which immunizes coordination between an undertaking and its employees or controlled entities¹⁶¹². In particular, the relationship between a platform and its business partners may be qualified as a genuine commercial agency, where a platform is working for the benefit of a principal and may be treated as an "auxiliary organ" forming an integral part of the latter's undertaking, who must carry out his principal's instructions and thus, like a commercial employee, forms an economic unity with the undertaking¹⁶¹³.

This immunity for commercial agents is typically justified on grounds of transactional efficiency, to foster the ability of firms to choose the most efficient governance structure to organize their production without being penalized for "contracting out" some of

1611 For the US "single entity" doctrine, see *Copperweld Corporation v. Independence Tube Corporation* (1984), 104 S. Ct. 2739; *American Needle, Inc. v. National Football League* (2010), 130 S. Ct. 2206. For the EU "single economic unit" doctrine, see *Case 22/71, Béguelin Import Co. v S.A.G.L. Import Export* [1971] ECR 949, para. 8; *Allgemeine Elektrizitäts-Gesellschaft AEG-Telefunken AG v Commission of the European Communities* [1983] ECR 3151, para. 50; *Case 170/83, Hydrotherm Gerätebau GmbH v Compact del Dott. Ing. Mario Andreoli & C. Sas.* [1984] ECR-2999, para. 11. *Case C-217/05, Confederation Espanola de Empresarios de Estaciones de Servicio v Compania Espaniolas de Petroleos SA (CEPSA)*, ECLI: EU: C: 2006: 784, para. 40. For an overview of the evolving standard in both jurisdictions, see Pieter Van Cleynebreugel, 'Single entity tests in U.S. antitrust and EU competition law', available at <http://ssrn.com/abstract=1889232>.

1612 The concept is also used in EU competition law to impose liability on an undertaking for the conduct of separate legal entities to the extent that there is a "unitary organisation of personal, tangible and intangible elements, which pursue a specific economic aim on a long-term basis and can contribute to the commission of an infringement of the kind in Article 81(1) EC". See *Case C-407/08 P, Knauf Gips KG v European Commission*, ECLI:EU:C:2010:389, 84.

1613 See, in the EU: *DaimlerChrysler AG v Commission of the European Communities* [2005] ECR II-3319, para. 85

their requirements to third parties. This understanding draws on the foundational work on Transaction Cost Economics (TCE) by Ronald Coase on the theory of the firm, and its subsequent development by Oliver Williamson¹⁶¹⁴ (see also our analysis in Chapter 3). Coase identified transaction costs as the reason why firms prefer to hire employees rather than to contract an independent party for one or more particular tasks; he thus explained that as a firm grows, so do the transaction costs involved in its internal processes, making the prospects of contracting out more appealing from an efficiency standpoint¹⁶¹⁵. Writing three decades later, Williamson focused on transaction costs as a defining element to distinguish between two opposite modes of production -hierarchies and markets- and further identify a third genus -hybrids- where the firm contracts out some of its functions while retaining some degree of coordination¹⁶¹⁶. He thereby illustrated the trade-offs involved in choosing one form over another, showing that choices will depend on the interaction between three types of attributes for each transaction: the specificities of assets involved, the uncertainties regarding the organization of the transaction, and its frequency. According to Williamson, this should lead to forbearance from interference with the firm's selected internal governance mechanisms because the firm constitutes the most efficient way of gathering knowledge about the circumstances of each transaction, and because permitting internal disputes to be appealed to court would undermine the efficacy and integrity of hierarchy.¹⁶¹⁷

However, a TCE view does not always adequately explain the strategic considerations involved in selecting a particular mode of production or distribution (see Chapter 2). This can be understood with reference to the work of Oliver Hart and John Moore, who took the theory of the firm one step further by linking it to ownership: firms enter into incomplete contracts because of the impossibility to predict all possible contingencies, and in doing so can retain residual rights of control (i.e., rights to reorder the deployment of assets in case a need for adaptation arises) over assets that are "contracted out"¹⁶¹⁸. Hart and Moore went on to argue that it is rational for firms to allocate ownership of productive assets to the party of the transaction which has the highest need for protection against *ex-post* opportunism over those incomplete contracts, which suggests a need for alignment between the hierarchy structure and the expected contribution of each actor in the value chain. In this sense, the commercial agency immunity would provide an important shield from liability for firms that need access to strategic resources (for instance, a platform's match-making capability) but seek to retain some level of control over the ability of the providers of those resources to influence the conditions of sale of the final product. In other words, a more strategic perspective justifies hybrid

arrangements in which a firm retains some form of ownership and control over a productive asset out of precaution against possible hold-up situations, even if this cannot be explained on purely transactional efficiency grounds. At the same time, a resource-based view suggests that there may be reasons to be concerned about firms using vertical arrangements to reach a position where the firm enjoys a competitive advantage over others being protected by imperfect substitutability and imperfect imitability.¹⁶¹⁹ The advantage may be the classic one of being the first mover, but it also applies to more intricate situations where the relationship between the resource and the competitive advantage is not immediately apparent (yet existent) or where it is difficult for other firms to replicate that resource due to complex social interactions¹⁶²⁰. A resource-based view recognizes the heterogeneity in firm's organization as a key factor in sustaining competitive advantage in the long run, along with the limited nature of competition (both *ex ante* and *ex post*) and the imperfect mobility of resources¹⁶²¹. In order to benefit from the immunity, an agreement needs to be one of *genuine* agency, as revealed from the substance of the arrangements made between the parties: a supplier cannot simply opt for the characterization of a relationship as "agency" to circumvent the application of the prohibitions of collusion and coordination under the antitrust rules. In order to identify the salient features of genuine agency and assess its application to online platforms, one can validly rely on guidance provided by courts and competition authorities—the most elaborate of which is found in the context of EU competition law¹⁶²².

The first important piece of guidance offered was the European Commission's Notice on exclusive dealing contracts with commercial agents¹⁶²³, which endeavoured to exonerate from the application of article 101 TFEU (formerly art. 85 TEC) the provisions of exclusivity between principals and genuine agents. The key criterion used by the Commission was financial risk: to qualify as genuine, the agent would need not to bear any financial risks bound up with the sale or performance of the contract¹⁶²⁴. The Notice illustrated specific scenarios in which it would consider this to be the case, namely when the contracting party: (a) is required to keep or does in fact keep, as his own property, a considerable stock of the products covered by the contract; (b) is required to organize, maintain or ensure at his own expense a substantial service to customers free of charge, or does in fact organize, maintain or ensure such a service; or (c) can or does in fact determine prices or terms of business. While it is not clear whether the qualification

1623 OJ 139, 24.12.1962, p. 2921–62.

1624 In addition to exclusivity provisions affecting competition in the market for products and services sold by an agent, the Notice extended immunity to exclusivity provisions affecting competition in the market for agency services. However, this was not on the basis of consideration of genuinity of the agency relationship, but rather on ground of its necessity in protecting the reciprocal interests of an agent and its principal.

of agent in those circumstances would amount to conclusive determination or rebuttable presumption, what transpired from this framework is a relatively simplistic view of ownership and control. This is understandable, considering that much of the ground-work on strategic management was yet to be laid out.

But the Notice included an additional complicating factor for the establishment of a commercial agency defense. In addition to the element of financial risk, a more general requirement for the putative agent was not to “undertake or engage in activities proper to an independent trader”. Subsequent Commission decisions provided clarification on this requirement by linking it to the concept of economic dependence, specifically focusing on the profitability and viability of the agent’s business separate from its relations with the principal¹⁶²⁵. The European Court of Justice initially went even further, suggesting that the existence of a relationship between the agent and suppliers other than the principal would be incompatible with the concept of genuine agency¹⁶²⁶. However, the same Court later seemed to reject the relevance of economic dependence in a seminal decision in *Volkswagen*¹⁶²⁷, by centering the whole inquiry on whether the putative agent would bear “any of the risks”. It should be noted that later decisions clarified that the notion of “any of the risks” should not be read too rigidly¹⁶²⁸, denoting that some degree of risk is acceptable. This leaves open the possibility of assessing the extent to which superior bargaining power is used to impose to another party the acceptance of a disproportionate degree of risk, which may in principle be used to pierce the veil of a putative agency¹⁶²⁹.

Against this backdrop, the Guidelines on Vertical Restraints¹⁶³⁰ adopted by the Commission in 2000 provided the opportunity to harmonize the approaches and simultaneously clarify the distinguishing elements of “genuine” agency. While the Guidelines reiterated the centrality of the criterion of financial or commercial risks, they also qualified the relevant risks into three types: contract-specific risks (such as financing or stock requirements); market-specific investments (e.g. requirements enabling the conclusion or negotiation of the contracts in question); and risks related to other activities that the principal requires the agent to undertake in the same product market (e.g. liability insurance, provision of pre-sale services). In doing so, the Guidelines restricted the type of risks considered material to the definition of agency by excluding any general risks taken in relation to the provision of agency services (e.g., investment in premises or personnel). The Guidelines therefore incorporated insights from the literature on the risk of ex-post opportunism, and its close link with relation-specific investments.

1629 This was indeed the case in a 2013 decision by the German competition authority finding a breach for an agreement between a hotel and a hotel reservation service: see *Bundeskartellamt, HRS-Hotel Reservation Service*, 9th Decision Division, B 9 – 66/10, Dec. 20, 2013

1630 Commission Notice on Guidelines on Vertical Restraints, OJ 2000 C 291/1.

Another key change in the Guidelines was the expansion of the breadth of the immunity to cover not only exclusivity provisions, but a broader range of restrictions including (a) limitations on the territory in which the agent may sell these goods or services; (b) limitations on the customers to whom the agent may sell these goods or services; and (c) prices and conditions at which the agent must sell or purchase these goods or services¹⁶³¹. However, this expansion is accompanied by an important *caveat*, ruling out the application of the immunity to agreements that facilitate collusion¹⁶³². This position, that was recently confirmed by the European Commission's investigations of Apple and its partners for the switch from a wholesale to an agency model for the sale of e-books¹⁶³³, is functionally equivalent to the carve-out designed by the US Supreme Court for agency agreements that enable a distribution system "to fix prices through many retail outlets"¹⁶³⁴. This policy recognizes the dual role of agency agreements, which can have substantial effects on competition in the market for the products and services sold by the agents, and prevents the immunity from being erected as a shield against the collusive outcome that can be achieved through a common agency framework. One may contend that in the pursuit of this goal, the policy may have cast too wide a net, as it subjects to scrutiny all agreements that *facilitate* rather than *enable* collusion.

However, the inapplicability of the immunity does not rule out the possibility for the conduct to be deemed compatible with article 101 (1), or to raise a defense under art. 101 (3). Furthermore, casting a wider net for facilitating practices is in line with the inferential approach used to deem collusion proven, in particular due to the secretive nature of cartels and the fact that they are typically investigated after a considerable lapse of time. Some concern can be expressed with regard to the extension of the same treatment in a vertical relationship to suppliers who lack knowledge or intent of the collusive outcome, in particular when it is the result of a supplier-initiated restraints¹⁶³⁵. It has been suggested that a more lenient approach could be followed in the latter scenario, with the exception of situations where there is upstream market power¹⁶³⁶—as that creates sufficient conditions of awareness justifying the extension of the inferential approach. A similar reasoning would support an inquiry into market power at the retailer level when assessing the competitive effects of retailer-initiated restraints¹⁶³⁷.

1631 Para. 18

1632 The Guidelines give two examples of this situation: when a number of principals use the same agents while collectively excluding others from using these agents; and when they use the agents to collude on marketing strategy or to exchange sensitive market information between the principals. *Ibid*, para. 20.

The Guidelines also considered the applicability of the commercial agency immunity to contractual provisions regulating the relationship between principal and agents, reasserting the Commission's lack of concern for exclusivity provisions (as in its 1962 Notice) but short of excluding it altogether from the application of competition law: the Commission merely refers to the absence of anticompetitive effects "in general", which implies that such agreements will not be covered by the immunity. Furthermore, a more restrictive view is taken with respect to the single branding and post-term non-compete agreements, holding that such provisions may infringe article 101(1) if they lead to or contribute to a (cumulative) foreclosure effect on the relevant market where the contract goods or services are sold or purchased¹⁶³⁸. The recognition of the role of intra-brand competition in affecting the conditions of sale in the market of the product or service sold by the agents highlights an important consideration in defining the boundaries of the agency immunity, which should correspondingly inform the analysis of agreements in platform markets. Taken at face value, this implies that a platform with substantial power in a particular product market (say, for instance, Uber with regard to transportation services) cannot invoke the commercial agency immunity for the prices it sets for its contractors entrusted with the delivery of that product (i.e., drivers), at least to the extent those contractors cannot be qualified as employees¹⁶³⁹. Yet, while such conclusion is dispositive once a situation of dominance or of significant impediment to intra-brand competition is established, in the absence of evidence to that effect it will be necessary to examine the conditions governing the relationship between platforms, its sellers, and final consumers. One may not also exclude if Uber's contractors are considered as 'undertakings' subject to the scope of competition law and not employees that Uber may be the hub of a hub and spoke conspiracy. The concept of 'hub and spoke conspiracy' is a form of indirect concerted practice, in particular through information disclosure among competitors, which combines a covert horizontal element and a vertical element, involving communications between suppliers and each of their customers¹⁶⁴⁰. However, it presents some "peculiarities" when compared to other forms of indirect concerted practice in that

"[...] they sit at the crossroads of various theories of harm: they may in fact be seen as nothing more than a spillover of normal vertical conduct; or considered as a sophisticated way in which horizontal cooperation or, at least, an exchange of information may be structured. They may equally be viewed as a practice having the same detrimental effects on competition as a cartel but without the typical

1638 Para. 19.

1640 On this concept, see inter alia O. Odudu, *Indirect Information Exchange: the Constituent Elements of Hub and Spoke collusion*, (2011) 7(2) *European Competition Journal* 205-242; P. J.G. Cayseele, *Hub-and-spoke Collusion: Some Nagging Questions Raised by Economists*, (2014) 5(3) *Journal of European Competition Law & Practice* 164-168; G. L. Zampa & P. Buccirosi, *Hub and Spoke Practices: Law and Economics of the New Antitrust Frontier?*, (2013) 9(1) *Competition Policy International* 91-110; Nicolas Sahuguet & Alexis Walckiers, *Hub-and-Spoke Conspiracies: the Vertical Expression of a Horizontal Desire?*, (2014) *Journal of European Competition Law & Practice* 5 (10): 711-716; Nicolas Sahuguet & Alexis Walckiers, *Selling to a cartel of retailers: a model of hub-and-spoke collusion*, (2013) CEPR Discussion Paper, No. 9385.

characteristics of a cartel. Further, to add to their peculiar nature, [hub and spoke conspiracies] may equally affect intrabrand and interbrand competition”¹⁶⁴¹.

This hybrid horizontal/vertical nature of “hub and spoke” conspiracies raises interesting issues of characterization of the cooperation between the undertakings involved (the collusion element) as well as their qualification as a restriction of competition (the restriction of competition element). With regard to this, an interesting case arose in India. In the case of *Samir Agrawal vs. ANI Technologies Pvt. Ltd. & Uber*¹⁶⁴², it was alleged that ride sharing platforms Ola and Uber were able to fix prices of the rides using algorithms. These fixed prices acted as an imposition of minimum resale price maintenance agreement between the ride sharing apps and their drivers as the latter have no liberty to reject the price calculated by the algorithm or offer their services at a price lower than the said price. However, the Competition Commission of India (CCI) held that there was no ‘resale’ as the platforms were not selling any service to the drivers which they could resell to the riders.

A number of focal questions can be considered relevant to signal the existence of an agency relationship, as opposed to one of distribution: does the platform buy or take ownership of the supplier’s product and assume liability in relation to it? Does it represent its suppliers and contract on their behalf? Does it owe fiduciary duties to act in the supplier’s best interest? And finally, is there a payment of a commission for the activity undertaken?

Each of these questions can be answered in different ways depending on the governance mechanisms adopted by the relevant platform: for instance, a platform for hotel reservations like Booking.com might take on itself the task to negotiate prices by applying special discounts, while that might not be a valid strategy for platforms that provides merely matchmaking services or that features goods satisfying longer term needs, like Etsy. The commission received by the platform might be dependent on sales or fixed, as well as a combination of the two, and might vary significantly if the platform chooses to assume liability *vis a vis* the final customers for the products or services it intermediates. Similarly, the extent of fiduciary duties will differ substantially depending on whether it is apparent that the platform operates as agent for multiple suppliers, and whether it is vertically integrated as a competitor in the market of the products or services being sold.

The question of the dual role of certain platforms remains particularly controversial because the Guidelines have failed to clarify its compatibility with the unity of interests ascribed to an agent and its principal, unlike for the situation of multiple competing principals, thus leaving an open question as to whether the commercial agency immunity can be validly raised in such circumstances. A recent study, drawing on comparative analysis between agency law, competition law, employment and tax law, suggested

1641 G. Zampa & P. Buccirosi, *Hub and Spoke Practices: Law and Economics of the New Antitrust Frontier?*, (2013) 9(1) *Competition Policy International* 91-110, 92.

1642 <https://www.cci.gov.in/sites/default/files/37of2018.pdf>

that the answer cannot, or in any case should not be in the affirmative¹⁶⁴³: the dual role produces a conflict of interest that is tension with the understanding of “single economic entity”, as well as an automatic cost advantage for the platform over its supplier which jeopardizes the core agency principle of “not making a profit at the principal’s expense”¹⁶⁴⁴. After reviewing the standard terms and conditions of six major platforms- Uber, Amazon Marketplace, eBay, Apple App Store, Airbnb and Booking-, the study concluded that such platforms “appear to be, on balance, independent contractors who are agents of their suppliers”¹⁶⁴⁵. In particular, this is the case as they lack ownership over the products or services for which they facilitate transactions, and exclude liability in relation to the performance of those contracts¹⁶⁴⁶; they undertake very limited risk in that regard, for instance relating to the provision of insurance or advertising, which can more generally be related to the platform market rather than the relevant product market¹⁶⁴⁷; and finally, they retain only minimal residual control rights, which appear to be necessary given the specificities of platform markets¹⁶⁴⁸. All in all, these contracts appear to demonstrate that platforms act as agents for their sellers. However, one should bear in mind that they are only of limited comfort for platform operators and their partners/suppliers, as the commercial agency immunity will in any case not apply where there is significant market power either in the market for platform services or in the separate market for products and services which are being sold through the platform. Furthermore, the relevance of considerations of economic dependency in the Court’s and Commission’s decisions reveals a concern not only with market power, but with the broader realm of superior bargaining power. This does not require evidence of market power in a traditional sense- focused on a firm’s ability to raise prices and reduce output¹⁶⁴⁹. As a result, to the extent that the restrictions are motivated not by transactional efficiency, but primarily by the use of superior bargaining power to capture value from a resource-based perspective, it is questionable that the default regime of immunity (or forbearance) should indeed apply.

It is also worth mentioning that the non-application of the agency immunity does not prejudice the substantive analysis conducted under article 101 (1) and 101 (3), which require a defendant to produce evidence indicating that any restriction of competition is ancillary to the adoption of a procompetitive measure, or, respectively, that the efficien-

1644 Ibid., 75

1645 Ibid., 57

1646 Ibid., 59

1647 Ibid., 51

1648 Ibid., 70-72. In particular, the “special” type of provisions are the following: first, clauses prevent suppliers from contacting parties outside the platform, so as to prevent disintermediation that would cause free riding on the platform’s match-making. Second, clauses allow the platform to discontinue relationships with suppliers, typically on ground of failing to meet certain quality standards.

1649 For an overview of the concept of superior bargaining power, see I.s Lianos and C. Lombardi, ‘Superior Bargaining Power and the Global Food Value Chain: The Wuthering Heights of Holistic Competition Law?’ Centre for Law, Economics and Society Research Paper Series: 1/2016

cies generated by the restraint outweigh their anticompetitive effects. This particular claim structure appears to be sufficient to address the concerns raised by commentators with regard to the rigidity of the commercial agency doctrine, which stems from a criticism about its focus on risk as opposed to the efficiency justifications that are examined under some case-law of the US Court of Appeals for the 7th and the 4th Circuit¹⁶⁵⁰. While the application of the commercial agency immunity should not lose sight of its efficiency-enhancing purpose, it remains an imperfect procedural shortcut and does not prevent deeper engagement with the procompetitive aspects of the restraints that fall outside of its scope. For this reason, it should be constructed narrowly and paying particular attention to the caveats that have been made in this Section.

6.2.3. Online distribution of content and competition law

Online distribution of digital content is intrinsically dependent on the applicable legal framework for the transmission of copyrighted works. International copyright law grants exclusive rights for authors of literary and artistic works¹⁶⁵¹ and for phonograms producers including the right to reproduce, distribute, rent and make available their work¹⁶⁵², as well as certain minimum rights for performers and broadcasting organizations including the right to prevent the rebroadcasting or fixation of their broadcasts, and the reproduction of fixations made without consent or outside the permitted exceptions¹⁶⁵³. Equivalent protections are laid down for members of the World Trade Organization as part of the Agreement on Trade-Related aspects of Intellectual Property (TRIPS agreement)¹⁶⁵⁴, and are then implemented at the national or regional (including EU) level¹⁶⁵⁵.

In the European Union, intellectual property has always been a matter of shared competence between the EU and Member States, meaning that the latter can intervene to the extent that the EU has not exercised its competence¹⁶⁵⁶. One implication of that has been a tension between the national protection of intellectual property, which is explicitly safeguarded by the Treaty¹⁶⁵⁷, and the principles of competition and free movement in the EU single market. This tension is resolved by recognizing that while national law is free to establish its rules on intellectual property rights EU competition law can limit the *exercise* of such rights granted. A concrete mechanism for limiting that exercise is

1650 Zhang, *supra* n. 25.

1651 Berne Convention for the Protection of Literary and Artistic Works, art. 10-14.

1652 WIPO Performances and Phonograms Treaty (WPPT) (1996), art. 11, 12 and 14.

1653 International Convention for the Protection of Performers, Producers of Phonograms and Broadcasting Organizations, art. 7 and 13.

1654 See in particular art. 9, 11 and 13

1655 EU law for instance harmonizes the rights to reproduction, distribution and communication to the public in articles 2-4 of Directive 2001/29/EC on the harmonisation of certain aspects of copyright and related rights in the information society.

1656 This has been changed by the Lisbon Treaty with regard to external policy on intellectual property, which pertains to EU's exclusive competence. See Art. 207 (1) TFEU.

1657 See in particular article 345 TFEU, according to which "The Treaties shall in no way prejudice the rules in Member States governing the system of property ownership".

the application of the principle of exhaustion, established for the first time in *Deutsche Grammophone*¹⁶⁵⁸ (and subsequently injected into various instruments of EU intellectual property law): once a copyright holder has exercised his or her exclusive right of distribution by putting his work on the market, that right can no longer be exercised. In the *Deutsche Grammophone* case, that meant that copyright could not be used to prevent parallel imports of the copyrighted work¹⁶⁵⁹. Such ruling aligned with another seminal case, *Consten v. Grundig*, where the ECJ used competition law to prevent artificial fragmentation of the EU market through a system of licenses granting absolute territorial protection, i.e. exclusive territorial licenses combined with prohibitions for other licensees to make deliveries outside their assigned territories. The difference between a so called “open” exclusive license and one with absolute territorial protection was reiterated some years later in *Nungesser*, noting that such protection manifestly went beyond what is indispensable for the improvement of production or distribution or the promotion of technical progress¹⁶⁶⁰. Ultimately, this line of cases led to the recognition of absolute territorial protection as a hardcore restriction of competition, which cannot benefit from the application of the exemption framework granted by the Vertical Block Exemption Regulation (with the exception of sales outside one’s place of establishment by a member of a selective distribution system)¹⁶⁶¹. It is also worth mentioning that the Commission notes in its Guidelines on Vertical restraints that absolute territorial exclusivity may be necessary for a certain period of time, generally two years, if the distributor is entering a new market where a significant investment is required¹⁶⁶².

The Court of Justice also considered the compatibility of exclusive licenses in the specific context of online distribution of copyrighted content in *Coditel*¹⁶⁶³. In particular, it clarified that the exhaustion principle does not find application with regard to the distribution of digital goods, where the availability to the public is separable from the circulation of the material form¹⁶⁶⁴. It then went further to explain that in this context, a system of exclusive territorial licenses would not necessarily restrict competition: it could be justified by the characteristics of the cinematographic industry, especially those relating to dubbing and subtitling, to the possibilities of television broadcast, and to the sys-

1664 This view was recently confirmed by the ECJ in *UsedSoft*, where it held that exhaustion of a computer program would require the acquirer to delete or make the original copy unusable at the time of resale. See Case C-128/11 *UsedSoft GmbH v. Oracle International Corp.*, ECLI:EU:C:2012:407 para. 78.

tem of financing cinematographic production in Europe¹⁶⁶⁵. In *Murphy*¹⁶⁶⁶, the Court confirmed that there is nothing anticompetitive in the use of exclusive territorial licenses for broadcasting. However, it took issue with the additional obligation inserted in licensing agreements that prevented the sale of decoder cards outside the licensed territory, and which operated in conjunction with a UK law that prohibited the supply and possession of foreign decoders. This constituted an infringement by object because it was designed to ensure compliance with the territorial limitation and therefore prohibit the broadcasters from effecting any cross-border provision of services¹⁶⁶⁷. The Court also importantly articulated for the first time, in evaluating the compatibility of the UK law with the freedom to provide services in EU, the view that the specific subject matter of copyright is to receive *appropriate* remuneration for the use of copyrighted work¹⁶⁶⁸, not to guarantee the right holders concerned the opportunity to demand the highest possible remuneration¹⁶⁶⁹. It went further to specify that in order to be appropriate, such remuneration must be reasonable in relation to the economic value of the service provided, in particular in relation to the actual or potential number of persons who enjoy or wish to enjoy the service; and even went as far as admitting that it may be appropriate to request a higher remuneration in the presence of territorial exclusivity¹⁶⁷⁰. However, it specifically ruled out that such remuneration could be given in exchange for *absolute* territorial exclusivity, because that would result in artificial price differences between the partitioned national markets¹⁶⁷¹.

The legality of absolute territorial licensing is a recurring issue for the European Commission, which recently triggered the investigation of Sky UK and six American film studios for contracts that included the reciprocal obligation not to respond to unsolicited requests outside the assigned territory (see *infra*, 5.3.1.1.)¹⁶⁷². While the investigation was closed with commitments offered to address the Commission's concerns, we should not take for granted that an exclusive license combined with a contractual prohibition of cross-border transmission constitutes an infringement of article 101 TFEU: such prohibition may indeed be justified where the transmission in question would amount to a copyright violation in the country of destination¹⁶⁷³.

1673 Pablo Ibáñez Colomo, 'Copyright licensing and the EU digital single market strategy'. LSE Law, Society and Economy Working Papers 19/2015, p. 10.

What is crucial is to verify whether the measure adopted by a copyright owner does not go beyond what is necessary to protect the right to receive an appropriate remuneration. EU caselaw shows that a similar assessment of compatibility would apply if the copyright owner were to adopt technological measures to prevent or restrict unauthorized acts with regard to a copyrighted work, for instance filtering and watermarking. In particular, the Court has held that copyright owners cannot prohibit the use of devices or activities which have a commercially significant purpose or use other than circumventing a technological protection measure for unlawful purposes¹⁶⁷⁴. This implies that, before granting protection against the use or distribution of a particular circumventing device, it will be necessary “to examine whether other measures or measures which are not installed [...] could have caused less interference with the activities of third parties by implying fewer limitations to those activities, while still providing comparable protection of that rightholder’s rights”¹⁶⁷⁵.

A similar reasoning has been followed in the US context to reject attempts to stretch beyond the scope of copyright the legal protection granted to the use of technological protection measures, such as Digital Rights Management systems.¹⁶⁷⁶ Considering that technological protection measures may be automatically enforced outside one’s jurisdiction, mechanisms to limit a copyright owner’s ability to extract profits beyond borders become particularly important. This is especially relevant for the enforcement of access and use restrictions in emerging economies like BRICS, where due to the prohibitive costs for the majority of the population piracy represents the main form of access to a variety of media goods¹⁶⁷⁷. As noted by a multi-country study focused primarily on Brazil, India, Russia and South Africa, the prevalence of multinationals media firms leads to business models that protect the pricing structure of high-income countries and prevent the emergence of competitors catering to the local needs¹⁶⁷⁸.

Against this backdrop, it is logical to expect in BRICS jurisdictions a different sensibility to restrictions against parallel imports from the one that prevails in the EU context. The difference is likely to transpire also with regard to the approach to copyright enforcement against online content-sharing platforms, which are now specifically subject under the new EU copyright directive to an obligation to seek authorization for making available the content they host¹⁶⁷⁹. Once again, it can be discussed whether the more strin-

1679 Directive 2019/790 on copyright and related rights in the Digital Single Market and amending Directives 96/9/EC and 2001/29/EC, OJ L 130, 17.5.2019, pp. 92-125, art. 17 (1). Failing authorization, those platforms are considered liable unless they demonstrate to have made best efforts to obtain an authorization, best efforts to ensure the unavailability of

gent regulations adopted in the EU context will necessarily provide a valid justification for restrictions included in licenses between copyright holders and platforms operating outside the EU, and for terms used by these platforms in their user agreements. This illustrates that the interlinkage of copyright and competition enforcement in online content distribution is likely to trigger more competitive issue than has historically been the case, specifically given the prominence of large multinational platforms and the insufficient coordination of local and inter-regional initiatives of platform regulation.

6.3. A bestiary of online vertical restraints: a comparative perspective

We briefly discuss some of the most common online vertical restraints below.

6.3.1. Restrictions on sales

6.3.1.1. Geo-blocking and geo-filtering

The recent efforts to promote a “digital single market” in the EU testify to the continuing relevance of the idea of economic integration and of the need to break down “national silos in telecoms regulation, in copyright and data protection legislation, in the management of radio waves and in the application of competition law”, all of which reduce the “great opportunities offered by digital technologies, which know no borders”¹⁶⁸⁰. The digital single market aims to allow seamless access for consumers and businesses to online goods and services across Europe. This may be affected by practices of ‘geo-blocking’ and ‘geo-filtering’.

Geo-blocking ‘refers to practices used for commercial reasons by online sellers that result in the denial of access to websites based in other Member States’¹⁶⁸¹. Geo-filtering consists of offering different terms and/or conditions depending on the location of the user, when situated in a different Member State than that of the online provider¹⁶⁸². Geo-blocking may occur even if consumers are able to access the website, when they are not able to purchase products or services from it, particularly when they are re-routed to a local website of the same company with different prices or a different product or service. Geo-filtering occurs when ‘geo-localising practices are used as a result of which different prices are automatically applied on the basis of geographic location, for example when online car rental customers in one ... State pay more for the identical car rental

specific works and other subject matter for which the rightholders have provided the service providers with the relevant and necessary information; and in any event acted expeditiously, upon receiving a sufficiently substantiated notice from the rightholders, to disable access to, or to remove from their websites, the notified works or other subject matter, and made best efforts to prevent their future uploads. See art. 17 (4).

1681 Commission Staff Working Document, Geo-blocking practices in e-commerce – Issues paper presenting initial findings of the e-commerce sector inquiry conducted by the Directorate-General for Competition, SWD(2016) 70 final, para. 32.

1682 Ibid., para. 33.

in a given destination than online customers in another ... State¹⁶⁸³. More generally, geo-filtering also may occur when online providers allow users to access and purchase consumer goods/digital content services cross-border, but offer different terms and/or conditions depending on the location of the user in a State different from that of the provider¹⁶⁸⁴. Geo-blocking or geo-filtering may be applied by various operators: retailers operating an online store, online marketplaces and price comparison websites¹⁶⁸⁵.

Following a sector inquiry whose initial findings were published in 2017¹⁶⁸⁶, the European Commission found that geo-blocking is applied by the majority of online digital content providers and is largely based on contractual restrictions, although it may also be adopted through unilateral conduct. The Commission also acknowledged the existence of 'technical geo-blocking', which aims to restrict a user's ability to access and use content in a given Member State from outside that Member State's territory (access and portability restrictions), which is often used for digital content services¹⁶⁸⁷. Technical geo-blocking may limit the user's ability to play previously downloaded content in certain territories, restrict the catalogue of content and/or services available to a given user in different territories, and inhibit the ability of an existing user to access the service in different territories¹⁶⁸⁸. One of the key findings of the sector inquiry was that almost 60% of digital content providers who participated in the inquiry have contractually agreed with right holders to "geo-block", as online rights are to a large extent licensed on a national basis or for the territory of a limited number of Member States which share a common language. According to the Commission, "(g)eo-blocking is most prevalent in agreements for TV series (74 %), films (66 %) and sport events (63 %). It is less prevalent in agreements for other digital content categories such as music (57 %), children's TV (55 %), non-fiction TV (51 %) and news (24 %)"¹⁶⁸⁹. The Commission stressed that any competition enforcement in relation to geo-blocking would have to be conducted on a case-by-case analysis of potential justifications for the restrictions imposed. The Commission's Staff Discussion paper makes it clear that limiting the ability of European users to shop online cross borders, 'may run counter to the objective of establishing a *single market*'¹⁶⁹⁰. Although market integration is a distinct objective of EU competition law, this may also be considered as an important competition concern in other jurisdictions.

Among the various tools, including the implementation of competition law, the European Commission has adopted specific rules prohibiting geo-blocking and geo-filtering that may raise barriers to cross-border online activity¹⁶⁹¹.

The CJEU took a quite restrictive position for absolute territorial restrictions included in licensing agreements for broadcasting services in *Premier League/Murphy*, where it was held that certain licensing provisions preventing a satellite broadcaster from providing broadcasts to consumers outside the licensed territory and thus granting him an absolute territorial exclusivity in the area covered by the license eliminated all competition between broadcasters, partitioned national markets and constituted a restriction of competition by object under Article 101(1) TFEU and cannot be justified under Article 101(3) TFEU.

The Commission has also taken a similar restrictive position with regard to licensing agreements preventing the cross-border provision of online pay-TV services through satellite to consumers outside the licensed territory. The Commission opened an investigation against Sky UK and each of six major US film studios (Disney, NBC Universal, Paramount Pictures, Sony, Twentieth Century Fox and Warner Bros) for having bilaterally agreed to put in place contractual restrictions that prevent Sky TV from allowing EU consumers located elsewhere to access, via satellite or online, pay-TV services available in the UK and Ireland.¹⁶⁹² According to the Commission's press release, such clauses limit Sky UK's ability to accept unsolicited requests for its pay-TV services from consumers located in other Member States and contain clauses requiring studios to ensure that in their agreements with other broadcasters they include clauses preventing them from making their pay-TV services available in the UK and Ireland. According to the Commission's press release, in the absence of these restrictions, 'Sky UK would be free to decide on commercial grounds whether to sell its pay-TV services to such consumers requesting access to its services, taking into account the regulatory framework including, as regards online pay-TV services, the relevant national copyright laws'. This competition law investigation forms part of the initiative of the Commission to examine contractual restrictions on passive sale outside the licensed territory in agreements between studios and other major broadcasters based in the EU, such as Canal Plus, Sky Italia, DTS in Spain, Sky Deutschland)¹⁶⁹³ and to reform the legislative framework, in the context of the Single Digital Market Strategy, in order to facilitate wider access to online content across borders in the EU.¹⁶⁹⁴ The proposed rules will also oblige online content service

1691 Regulation (EU) 2018/302 of the European Parliament and of the Council of 28 February 2018 on addressing unjustified geo-blocking and other forms of discrimination based on customers' nationality, place of residence or place of establishment within the internal market and amending Regulations (EC) No 2006/2004 and (EU) 2017/2394 and Directive 2009/22/EC, [2018] OJ L 601/1 (hereinafter Geo-blocking Regulation).

1693 European Commission, Press Release, Antitrust: Commission investigates restrictions affecting cross border provision of pay TV services (January 13, 2014), available at europa.eu/rapid/press-release_IP-14-15_en.htm.

1694 See, for instance the Commission's proposals to modernise EU copyright rules and review the EU Satellite and Cable Directive: Council Directive 98/93/EEC of 27 September 1993 on the coordination of certain rules concerning copyright

providers to offer cross-border portability to their subscribers who are temporarily outside their home country.¹⁶⁹⁵

Brazil: Resolution CADE 20/99 has a specific provision on territory restrictions and customer base, by which the manufacturer determines geographic boundaries to the operation of the distributors or dealers. Accordingly, practices of this nature may restrict competition and competitors' entry in several regions, facilitating collusive practices and unilateral increases of manufacturers' market power. Nevertheless, considering that the practice shall be analysed under the rule of reason, Resolution CADE 20/99 also provides that the possible benefits in terms of transactional cost savings should be taken into consideration when reviewing these cases.

6.3.1.2. Online sale bans and platform bans and restrictions

A retailer may sell its goods through a well-known platform if it is able to gain greater exposure to customers than if it were to operate exclusively under its own brand. This is similar to the shop-in-shop concept, in which a retailer is granted a concession in a larger retailer outlet. The concessionaire benefits from the foot-fall that is already attracted to the retail location.

A number of supply systems are organised in the form of what has been called 'selective distribution', in which the suppliers limit the number of distributors that can join their distribution networks, requiring distributors to satisfy certain conditions. Although selective distribution provides considerable benefits to consumers, as it promotes quality certification, which is particularly important for certain categories of products (e.g. luxury goods, electronic goods etc.) it may also lead to the exclusion of some purely online distributors from the possibility to participate to some distribution networks. Online retailers and marketplaces are also reluctant to incur the costs implicit in a selective distribution system and have been quite active in demanding a strict application of competition law so as to limit the possibility of suppliers to impose restrictions in their selective distribution networks as to online sales, discriminating between offline and online commerce, such as online sales' bans, restrictions on marketplaces in the context of an online selective distribution system, or bans to use price comparison tools.

There is significant case law on these issues in the EU, both at the EU competition law and national competition law levels¹⁶⁹⁶. With regard to bans on online sales, a survey of the case law in various member States, the OECD summarize the state of the law as follows:

and rights related to copyright applicable to satellite broadcasting and cable retransmission [1993] OJ L 248/15.

1695 European Commission, Press Release, Commission takes first steps to broaden access to online content and outlines its vision to modernise EU copyright rules (December 9th, 2015), available at europa.eu/rapid/press-release_IP-15-6261_en.htm. The new framework emerging out of these initiatives will enable people to use services such as video streaming in order to access content on Netflix, iPlayer, Amazon Instant Video and HBO Go, requiring these streaming services to open their local content library in any EU member state.

1696 See, C-439/09 *Pierre Fabre Dermo-Cosmétique SAS v Président de l'Autorité de la concurrence and Ministre de l'Économie, de l'Industrie et de l'Emploi* [2011] ECR I-9419; Case C-230/16, *Coty Germany GmbH v Parfümerie Akzente GmbH*, ECLI:EU:C:2017:941.

The case law on perfumes and high-end cosmetics supports the argument that, whenever a selective distribution system is justified for luxury or experience goods, suppliers may impose restrictions on Internet sales that have the objective to protect the demand enhancing investments made either by the manufacturer or by the retailers. One way to achieve this objective is to allow only those retailers that also run a brick-and-mortar outlet to operate on the Internet. The idea is that these retailers have an interest in preserving the value of the investments that they have made in the physical point of sale and that they would internalize, at least partially, the negative effects that inappropriate e-commerce practices would have on these investments. In order to have an effective alignment of interests, sales in the physical shop must be relevant and this justifies also the imposition of quantity limits on Internet sales. These restrictions prevent the operation of a pure on-line distributor. However, a complete ban of on-line sales or the application of discriminatory conditions that would impede their development is still presumed to be illegal and the parties have the burden to prove that there exist “objective” justifications for such measures [...] Of course, much depends on the standard of proof that it will be required to prove the existence of “objective” justifications and whether the manufacturer will be also asked to show’.¹⁶⁹⁷

The Commission has also examined in its recent e-commerce enquiry whether restrictions on the use of marketplaces or price comparison tools can amount to a restriction of competition by object.

Although online sales bans are prohibited under EU competition law, in *Pierre Fabre*, the CJEU opened some possibilities for justification, under Article 101(3) TFEU, but excluded as a legitimate justification the objective of preserving brand image or other economic justifications.¹⁶⁹⁸ In *Coty*, the CJEU held that suppliers of luxury goods can prohibit the members of their selective distribution system from making online sales through discernible third-party platforms, to the extent this is appropriate to preserve the luxury image of those goods, this prohibition being compatible with Article 101(1) TFEU and not a restriction of competition by object¹⁶⁹⁹. The CJEU distinguished between a platform ban, which is permissible, as it only restricts a specific kind of online sale¹⁷⁰⁰, and an absolute ban on internet sales, which is not permitted under Article 101(1) TFEU and which forms a restriction of competition by object following *Pierre Fabre*¹⁷⁰¹.

¹⁶⁹⁷ OECD, Vertical Restraints for On-line Sales, DAF/COMP(2013)13, 34.

¹⁶⁹⁸ C-439/09 *Pierre Fabre Dermo-Cosmétique SAS v Président de l'Autorité de la concurrence and Ministre de l'Économie, de l'Industrie et de l'Emploi* [2011] ECR I-9419.

¹⁶⁹⁹ Case C-230/16, *Coty Germany GmbH v Parfümerie Akzente GmbH*, ECLI:EU:C:2017:941, para. 51.

¹⁷⁰⁰ *Ibid.*, para. 52. See also, the Opinion of AG N. Wahl in Case C-230/16, *Coty Germany GmbH v Parfümerie Akzente GmbH*, ECLI:EU:C:2017:603 (arguing that a supplier restricting its authorised distributors in a selective distribution system to sell the contract products via third party platforms cannot, in the present state of development of e-commerce, be assimilated to an outright ban on or a substantial restriction of internet sales, in particular if authorised distributors are allowed to distribute the contract products via their own internet sites).

¹⁷⁰¹ C-439/09 *Pierre Fabre Dermo-Cosmétique SAS v Président de l'Autorité de la concurrence and Ministre de l'Économie, de l'Industrie et de l'Emploi* [2011] ECR I-9419.

The European Commission also took the view that restrictions on the use of marketplaces ‘do not have as their object a restriction of the territory or the customers to whom the retailer in question may sell or the restriction of active or passive sales to end users’, they are ‘not aimed at segmenting markets in the internal market based on territory or customers’¹⁷⁰², and consequently an absolute ban on the use of marketplaces should not constitute a hardcore restriction¹⁷⁰³. However, the Commission envisages the possibility that bans on the use of marketplaces may be found incompatible with EU competition law depending on the circumstances¹⁷⁰⁴, such as the ‘importance of marketplaces as an online sales channel in relation to the product and geographic market in question, the type of restrictions applied (absolute ban or qualitative criteria) as well as the credibility of brand protection considerations and the need for pre- and post-sale advice will be important elements in the analysis’ or the fact that ‘the manufacturer has accepted the marketplace operator as an authorised seller within its selective distribution agreement’, the latter making brand protection considerations ‘less convincing’¹⁷⁰⁵.

The EU e-commerce Sector Inquiry Report also considers the compatibility with EU competition law of bans to use price comparison tools¹⁷⁰⁶. Price comparison tools compare prices of different retailers and establish extensive price transparency in retail markets with standardised products. The actual sale takes place on the website of the (authorised) retailer. Their use can be prevented by absolute bans, or the prohibition of the use of brand names as search terms, among other practices¹⁷⁰⁷.

Against the backdrop of the above discussion in the European Union, it is interesting to note that the trend in some BRICS jurisdiction has been in a different direction, namely to see e-commerce platforms as a crucial vehicle for the implementation of selective distribution, rather than as a channel potentially jeopardizing the goodwill that such selective distribution is aimed to promote.

Brazil: The Brazilian Competition Law does not provide for any specific guidance in respect to selective distribution. Nevertheless, an assessment by CADE will likely be made under the rule of reason on a case-by-case basis, balancing the anticompetitive effects and the economic efficiencies of the practice. In addition, the assessment would likely relate to some of the provisions established by Resolution CADE 20/99 for restrictions on territory and customer base or refusal to deal. Their potential anticompetitive effects, therefore, could be related to blockage to, and increase in, barriers to entry into the distribution or supply channels.

India: India indeed offers one example of a selective distribution system enforced through removal from a platform of all products sold by unauthorized resellers. In *Ashish Ahuja v Snapdeal*, Mr. Ashish Ahuja who sells, among other things, certain SanDisk

1702 Commission Staff Working Document E-commerce, para. 508.

1703 Section 4.4.8. of the Commission Staff Working Document E-commerce.

1704 European Commission, Final report on the E-commerce Sector Inquiry, COM(2017) 229 final, para. 43.

1705 Commission Staff Working Document E-commerce, paras 513-514.

1706 Section 4.5.4. of the Commission Staff Working Document E-commerce.

1707 Commission Staff Working Document, p. 166.

products, lamenting that Snapdeal had stopped the sale of his items on its online e-commerce platform. The complainant argued that this action was taken pursuant to a restriction imposed by Snapdeal that only authorized vendors sell SanDisk products on its platform, which was in itself a requirement introduced upon agreement with SanDisk. Although the complainant alleged that the agreement between Snapdeal and SanDisk violated provisions of Section 3 of the Competition Act, which deals with anti-competition agreements, no specific provisions of Section 3 was alleged to have been infringed. CCI held that “insistence by SanDisk that the storage devices sold through the online portals should be bought from its authorised distributors by itself cannot be considered as abusive, as it is within its rights to protect the sanctity of its distribution channel”. SanDisk had earlier issued a circular that the full range of sales and warranty services available for its products would be available to only those SanDisk products brought from its authorised national distributors.

More interestingly for purposes of the interaction between offline and online, the CCI in this case defined the relevant market quite broadly. It observed that buyers tend to weigh the options available to them in offline and online markets before making a final decision, taking into account the differences in discounts and shopping experience. A significant increase in price in one segment will cause the buyer to shift to the other segment and therefore “these two markets are different channels of distribution of the same product and are not two different relevant markets.”

Other cases revolve around the effects of exclusive dealings on platforms. In *Mohit Manglani v Flipkart and others*, the informant complained that India’s e-commerce websites had entered into exclusive agreements with sellers of goods and services violating provisions of section 3(4) of the Competition Act, which prohibits vertical agreements between manufacturers and distributors if they cause or is likely to cause appreciable adverse effect on commerce in India. Further, the complainant alleged that each e-commerce platform had a 100 per cent market share for the product that was exclusively available only on their e-commerce platform, therefore leading to an abuse of such dominant position.

The CCI held that vertical agreements between producers of goods and services with the e-commerce firms does not result in an appreciable adverse effect on commerce. It reasoned that:

“It does not seem that such arrangements create any entry barrier for new entrants. It seems very unlikely that an exclusive arrangement between a manufacturer and an e-portal will create any entry barrier as most of the products which are illustrated in the information to be sold through exclusive e-partners (OPs) face competitive constraints.”

With respect to the allegation of abuse of dominant position by e-commerce firms, the CCI refused to accept the complainant’s narrow definition of the relevant market. The complainant had argued that if a given book is exclusively distributed through an e-commerce firm, it is not substitutable by another book distributed by brick-and-mortar

stores, hence making it a separate relevant market. The CCI disagreed, holding that individual products cannot be construed as a relevant market by themselves. Further, the CCI held that irrespective of whether it considered e-commerce market as a separate relevant product market or as a sub-segment of the overall market for distribution, it was of the view that none of the e-commerce platforms was individually dominant in either the overall distribution market or for the online segment, and therefore an assessment of the alleged abuse of dominance by such e-commerce firms was not required.

It is worth noting that since the CCI's order, Flipkart has been acquired by Walmart and as Amazon weighs up its presence in the Indian e-commerce market, with rumours of Reliance's imminent launch of its own e-commerce platform, the market share of e-commerce firms is constantly fluctuating over time. Future assessments by the CCI in the future may result in different conclusions, if the regulator finds that a particular e-commerce firm was individually dominant in India.

Furthermore, an overview of the Indian legal framework on platform restrictions cannot be complete without mentioning the recently adopted (February 2019) Foreign Direct Investment Policy on E-Commerce, where the government restricted e-commerce companies from selling products of companies in which they have an equity interest. It also prevented e-commerce companies from entering into exclusive agreements with sellers. The Policy states as follows¹⁷⁰⁸:

- An entity having equity participation by e-commerce marketplace entity or its group companies or having control on its inventory by e-commerce marketplace entity or its group companies, will not be permitted to sell its products on the platform run by such marketplace entity.
- e-Commerce marketplace entity will not mandate any seller to sell any product exclusively on its platform only.

6.3.2. Price discrimination and targeting

The internet enables advertising to be targeted or personalised.¹⁷⁰⁹ Datafication may enable firms to develop personalised pricing strategies. Behavioural pricing or personalised price discrimination, person-specific pricing, a species of first degree price discrimination, arises when sellers charge different prices to different buyers based upon each buyers elasticity of demand.¹⁷¹⁰ It is possible that such practices may be qualified

as a form of price discrimination prohibited by competition law or other statutes.¹⁷¹¹

Price discrimination is objectionable when a price difference is not justified by a cost difference. Need to distinguish online v offline, where costs differ, from other cases of differential pricing. In the EU, one condition for such practice to fall under Article 102(c) TFEU is that “other trading partners” are placed at a “competitive disadvantage”, which may suggest that this provision may not apply to discrimination on price or other parameters of competition against final consumers. However, this language has not prevented the Commission from apply Article 102(c) to final consumers in *Deutsche Post*, in particular consumers of postal services, which due to the behaviour of Deutsche Post were affected negatively by having to pay prices for these services which were “higher than those charged to other senders and by having their mailings delayed significantly” The Commission noted that:

“Article [102 TFEU] may be applied even in the absence of a direct effect on competition between undertakings on any given market. This provision may be also be applied in situations where a dominant undertakings behaviour causes damage directly to consumers”.¹⁷¹²

Further, the case law does not require evidence of a competitive disadvantage, which in some cases has been presumed.

It might be argued that personalised pricing is contrary to Article 102(a), the claim being that such pricing amounts to an “unfair purchase or selling prices or other unfair trading conditions.” This is examined in the relevant chapter concerning abusive practices. At first sight, dynamic pricing, real time pricing and price optimization do not raise competition law concerns to the extent they are unilaterally adopted and do not form part of a collusive scheme.

6.3.3. Across Platform Parity Agreements (APPAs)

Most favoured customer (MFC) or Most Favoured Nation (MFN) clauses, also called parity clauses or Across Platform Parity Agreements (APPAs), have also recently attracted the attention of competition authorities. These are broadly defined as agreements under which a seller agrees that a buyer will benefit from terms (e.g. prices) that are at least as favourable as those offered by the seller to any other buyer.

There are two main types of MFC: Wholesale MFC (or merchant model of MFC) denotes the situation when the terms relate to the wholesale part of the value chain, for instance the agreement governs the price at which a supplier will sell to an online distribution platform. The upstream supplier offers the product to a retailer at wholesale terms and

1711 See, for instance Article 102(c) TFEU. See, Autorité de la Concurrence & Bundeskartellamt, Competition Law and Big Data (May 10th, 2016), 21-22, noting that although the application of EU competition law to these practices may be debated, in Germany, the Federal Supreme Court found that the national provision against the abuse of a dominant position can include a consumer protection dimension as regards price discrimination, see German Federal Supreme Court (BGH), „Entega II“, KZR 5/10, judgment of 07.12.2010.

1712 Commission Decision COMP/C.1/36.915, *Deutsche Post AG*, [2001] OJ L331/40 (not appealed), para 133.

the retailer sets the retail price to consumers. An example of merchant MFC is, for instance, an agreement between a hotel and some online travel agencies (OTAs) through which the hotel guarantee the OTAs that they will benefit from the best room prices among those offered to all OTAs. As the parties discipline the price of their own transaction and the retailer keeps his freedom to set the retail price, these types of MFC may not be considered as *prima facie* problematic.

Retail MFC relate to the terms at the retail level, the supplier committing to the distribution platform to charge a retail price for its product(s) on this platform that are at least as low as the prices it charges on rival platforms. In the 'Agency' Retail MFC model, the upstream supplier sets the final retail price and splits profits with the retailers downstream, by paying them directly for their services. This has been the standard business model for online retail platforms, such as eBay or Amazon marketplace. The use of the term 'agency' does not indicate that the agreements constitute genuine commercial agency agreements, in the sense of the 2010 vertical restraints guidelines or the CJEU's case law on commercial agency, as the retail platforms do not always fulfil the criteria of the genuine commercial agency, but highlight simply the fact that the supplier sets the final price at the retail level. One may characterise them as shopping malls or even providers of an important input to the upstream suppliers, 'access to customers and sales logistics services'¹⁷¹³ but this characterization should not substitute for a careful analysis of the various aspects of the relationship and the allocation of costs, as one should do for the implementation of the conditions of the genuine commercial agency agreements' immunity to Article 101(1) TFEU. In contrast to wholesale MFCs, in retail MFCs the parties do not agree on a pricing obligation that concerns their own transaction but aim to discipline the price charged by the seller with a third party (the customers).

Depending on the factual context, retail MFC may have pro-competitive justifications. First, the use of a MFC may provide a platform the possibility to address a free rider problem, both at the wholesale and the retail levels, since competing online platforms, brick and mortar stores, or even the supplier through a direct sale on his own website may free-ride on a platform's investment in promotion and demand-enhancing features. This problem may be exacerbated in multi-sided platforms, which typically maximise their profits by charging different prices at each side of the market: a 0 price for the consumers, while they impose a commission/fee on the suppliers' side of the market. For instance, hotel may free-ride on an online travel agent (OTA) platform by using the platform to allow the customer to find the hotel, but then charge lower rates, if the customer completes the reservation at its own website, thus enabling the hotel to avoid paying the commission it would have owed to the platform, had the customer completed his reservation at the OTA platform.¹⁷¹⁴ Second, the use of MFC may protect the interests of a buyer who needs to make relationship-specific investments, by providing him the assurance that the seller will not provide the product to competing buyers

1713 A Fletcher and M Hviid, 'Retail Price MFNs: Are they RPM 'at its worst?' (April 7, 2014), available at competitionpolicy.ac.uk/documents/8158338/8199490/CCP+Working+Paper+14-5.pdf/0ec21eee-12ca-4bc8-b3ea-d5076ab264af, 7.

at a lower price.¹⁷¹⁵ This preserves the incentives of the buyer to invest in quality and reputation. Such clauses also reduce transaction costs, by avoiding the re-negotiation of prices, as the buyer will benefit from the price reductions granted to competitors automatically.¹⁷¹⁶ More generally, MFCs reduce the likelihood of contractual negotiation delays, as the parties are discouraged to delay in the expectation of a better offer.¹⁷¹⁷

A retail MFC may produce various anti-competitive effects. They can restrict entry at the retailer level by making it harder for new platforms, in particular those pursuing low-end business models, to attract suppliers, even if they lower their commissions/platform fees.¹⁷¹⁸ They help protecting intermediaries from direct selling by manufacturers or rival platforms, thus potentially leading to higher prices for consumers, if the competitive pressure is higher downstream than upstream.¹⁷¹⁹ This, in turn may, however, raise, under certain circumstances market-entry incentives.¹⁷²⁰ They act to soften competition between retailers and online platforms increasing the fees/commissions paid by the suppliers, these costs being ultimately passed on to consumers who finish by paying higher prices. They may be used as a means to achieve downstream collusion, as they reduce the incentives of retailers to deviate from a collusion on commissions/platform fees and they eliminate price competition at the retail level, as they remove any incentive for the retailer to undercut its rivals. But they can also facilitate collusion between suppliers upstream, as the reduction of price deviations across platforms make it easier to detect deviations from the collusive price. Finally, where only some platform providers use the agency model, a MFC leads to retail prices that resemble the outcome under industry-wide (collective) RPM.¹⁷²¹ The extent of retail competition on parameters not covered by MFCs, such as customer service and other quality-based competition, should also be relevant in the assessment of this impact.¹⁷²² The existence of cumulative effects, with a widespread use of MFN clauses in an industry, covering a substantial part of a market also raises important concerns¹⁷²³.

With regard to the effects of retail price MFC, one may distinguish between wide-MFC and narrow-MFC. In wide-MFC the price-setting supplier commits to charge the same price across all platforms and thus not to sell at a lower retail price anywhere else than it does through the retailer to which he conceded the retail price MFC. Narrow-MFC only require a supplier to charge the same price to consumers as it offers through a specific named retail platform. Naturally, the effect of wide-MFN is that the supplier needs to

control the retail price of its product everywhere it is sold.¹⁷²⁴ From this perspective, wide-MFN have been compared to RPM clauses, in view of the horizontal element of RPM, whereby each upstream firm sets identical retail prices across all of its downstream retailers.¹⁷²⁵ Those adhering to the RPM analogy conclude that retail price wide-MFC should not be treated less harshly than RPM, which implies that in the EU these should be considered as a by object restriction of competition and possibly a hardcore restriction under the Block Exemption Regulation.¹⁷²⁶ Some argue that the harm arising from retail wide-MFC can go beyond the harm that arises from traditional RPM, as the on-line retailer is controlling the minimum price that is being set in the market and can manipulate that price by increasing its commission, which is not possible under classic RPM.¹⁷²⁷ Others observe that MFCs are unlikely to harm competition where the level of concentration in both markets is low and the parties to an MFC lack market power.¹⁷²⁸

Competition authorities in Europe have dealt with a number of MFC cases, both wholesale and retail, the last few years. The use of 'wide' MFN clauses by intermediaries (ie price comparison websites or booking platforms) has been at the focus of many competition authorities' investigations. Most usually, the retailers force suppliers to implement MFC clauses in order to induce consumers' single-homing (ie, preventing them from consulting other platforms) thus being able to exercise market power even without being dominant (each platform becoming an unavoidable trading partner).

In 2002, the European Commission launched an investigation for a number of MFC clauses included in the contracts of eight major Hollywood studios ('the Majors') with Pay-TV providers. The contracts included 'output deals' between the 'Majors' and the European pay-TV broadcasters that bought the broadcasting rights, the studios agreeing to sell to broadcasters their entire film production for a given period of years. The MFC gave the studios the right to enjoy the most favourable terms agreed between a pay-TV company and any one of them. The Commission found that the cumulative effect of the clauses is an alignment of the prices paid to the Majors, as any increase agreed with a Major triggered a right to parallel increases in the prices of the other studio (cumulative collusive effect). The Commission closed the investigation after a number of majors accepted to withdraw the MFC clauses from the contracts¹⁷²⁹.

MFC were also examined in the more recent *e-books* investigation, following the switch from five main publishers from a wholesale model to an agency model for the sale of e-books in the United States, but also UK, France and Germany, each publisher concluding an agreement with Apple according to which the publishers determined the retail price

of the e-books it sold. These agreements with Apple formed part of a joint effort by the publishers to force Amazon to raise retail prices, which were set at 9.99 USD. In particular, the Commission was concerned that the joint switch to the agency contracts may have been coordinated between the publishers and Apple, as part of a common strategy aimed at raising retail prices for e-books or preventing the introduction of lower retail prices for e-books on a global scale. Indeed, the five publishers proposed to Apple an agency model for the sale of e-books and asked Apple to propose retail prices. The Commission was also concerned by the fact that these contracts contained the same key terms for retail prices – including an MFC clause, maximum retail price grids and the same 30% commission payable to Apple. The retail price MFC clause provided that, in the event another retailer were to offer a lower price for a particular e-book, including in situations where that retailer was operating under a wholesale model and thus was free to set retail prices, the publisher had to lower the retail price of that e-book in the iBookstore to match that other lower retail price. According to the Commission, the retail MFC clause ‘created a strong incentive for each of the Five Publishers to convert Amazon (and other major retailers [...]) to the agency model in order for each of the Five Publishers to be able to increase retail prices above those set by Amazon’. It also meant that, ‘had Amazon refused to convert to the agency model for UK titles, each of the Five Publishers would have had strong incentives to delay or withhold e-book new releases from Amazon’.¹⁷³⁰ After a preliminary assessment, the Commission found a horizontal/vertical concerted practice between the five publishers and Apple to raise retail prices in the EEA or to prevent the introduction of lower retail prices in the EEA, which it found had, by its very nature, the potential to restrict competition, that is was anticompetitive by object. The Commission accepted commitments by the parties, which placed a five-year ban on price MFCs, and required publishers to terminate their existing agency agreements with e-distributors and conclude new agreements that would allow agents to discount within their commissions.

A number of NCAs have also launched inquiries into MFCs in the online booking sector. Online Travel Agents (OTAs), such as Expedia, Opodo, Sabre, Booking.com and other members of the Priceline group, Voyages SNCF.com etc, have been a major e-commerce activity in recent years, as they are used by consumers in order to search, compare and book travelling and hotels. These online retail platforms also ensure the hotels’ visibility to consumers through the OTA’s webpage and advertising on search engines.

The UK OFT (the CMA’s predecessor) was the first authority to launch a formal investigation into vertical agreements concluded between hotels and OTAs in 2010 for breach of Chapter I CA 98 and Article 101 TFEU. Although not directly targeting MFC clauses, the OFT was concerned by the ‘discounting restrictions’ included in agreements between InterContinental Hotels Group and Hotel Inter-Continental London Limited (IHG) and each of Booking.com and Expedia, which prevented the online travel agents from discounting the price of room-only hotel accommodation. The OFT analysed the impact of retail rate MFCs clauses on the ability of OTA’s to offer discounts, these agreements requiring the

1730 E-BOOKS (Case No. COMP/39.847) (July 25, 2013), available at ec.europa.eu/competition/antitrust/cases/dec_docs/39847/39847_27536_4.pdf.

hotels to provide an OTA with access to a room reservation at a booking rate no higher than the lowest booking rate of any other online distributor (wide-MFC). Taking into account the efficiencies argued by the parties, the OFT accepted formal commitments from IHG, Booking.com and Expedia in January 2014¹⁷³¹, according to which the OTAs and the hotels would be free to offer reductions off headline room rates but these discounts would only be offered to members of ‘closed groups’ of consumers (‘club members’, membership being contingent on opting in and providing some personal details) and only applied when a customer had made a previous non-refundable booking with that OTA. OTAs would be able to publicize to non-club members the availability, but not the level, of discounts for IHG hotel rooms. Any discounts offered by OTAs were to be funded from their commission revenues or margin. The hotels would also be free to offer reductions off their headline room rates. The parties took also the commitment to amend, not include or remove any contractual provisions, including MFCs, that could reduce the freedom of the hotels to offer discounts.

The OFT’s decision was quashed by the CAT, as a result of a challenge from Skyscanner, a meta price comparison website, merely for the part of the decision that was limiting the disclosure of the level of discounts to members of the ‘closed group’, which affected the business model of Skyscanner.¹⁷³² The CAT remitted the case back to the CMA for reconsideration and the CMA decided to close the investigation into discounting restrictions on administrative priority grounds in September 2015, in view of the Europe-wide changes introduced by Booking.com and Expedia in their contracts in Europe with hotels, which removed certain ‘rate parity’ or ‘most-favoured-nation’ restrictions that prevent hotels from offering cheaper room rates on competing online travel agents’ sites than they offer on Booking.com or Expedia. The new arrangements allow hotels across Europe to offer cheaper rates than on Booking.com or Expedia through other online travel agents, offline, and to certain groups of customers. However, they continue in relation to prices offered on hotels’ own websites and certain other direct sales channels.¹⁷³³

In Germany, there have been independent court proceedings as well as action by the German Competition Authority (Bundeskartellamt) on the same issue. In interim proceedings, in 2012, the Düsseldorf Court of Appeal prohibited an online hotel booking platform, the Hotel Reservation Service (HRS), from implementing MFCs included in its contracts with hotel partners, as these clauses restricted the hotel’s freedom to set prices independently and deprived customers of the opportunity to obtain a better offer for the same hotel room on other sales channels (*wide*-MFC clause). By a decision in 2013, the Bundeskartellamt prohibited HRS’s MFCs ordering it to remove these clauses from all contracts, considering that these clauses restricted competition between OTAs,

1731 OFT 1514dec, Hotel Online Booking: Decision to accept commitments to remove certain discounting restrictions for Online Travel Agents, (January 31, 2014), available at webarchive.nationalarchives.gov.uk/20140402142426/http://www.of.gov.uk/shared_of/ca-and-cartels/oft1514dec.pdf.

1732 Skyscanner Limited v CMA [2014] CAT 16.

1733 CMA, Press Release, CMA closes hotel online booking investigation (September 16, 2015), available at www.gov.uk/government/news/cma-closes-hotel-online-booking-investigation.

prevented new platforms from offering hotel rooms at lower prices and restricted the opportunities open to hotels to use different sales channels in order to make offers at different prices and other conditions.¹⁷³⁴ The Bundeskartellamt did not distinguish between wide and narrow MFCs. It also left open the possibility of HRS's contracts to be exempted under the VBER, as HRS held a market share above the 30% threshold. The Düsseldorf Court of Appeal confirmed the decision of the Bundeskartellamt in January 2015 finding that HRS's 'best price' clauses restricted competition to such a degree that they cannot be exempted under the TFEU Block Exemption Regulation or as an individual exemption.¹⁷³⁵ The Court rejected HRS's claim that the MFC created incentives for ongoing investment in the quality of the downstream online platform, because of free-rider problems reducing sales downstream, as it found that OTAs had in any case considerable incentives to invest in the quality of their portal, as the more users a platform attracts on both the supply and the demand side the more appealing it becomes for new users. Most recently, however, the Düsseldorf Court of Appeal annulled another decision of the Bundeskartellamt that prohibited Booking.com to operate *narrow* MFN clauses with regard to hotels located in Germany¹⁷³⁶. It found the clauses to be necessary to ensure a "fair and balanced contractual exchange of services between the portal and the hotels", and therefore not amounting to a restriction of competition. The same outcome was reached in May 2019 in Sweden, where an appeal court reversed the first instance court's ruling in a case involving Booking and the Swedish hotel association Visita, finding that that the appellee had presented insufficient evidence that *narrow* MFNs had an anticompetitive effect¹⁷³⁷.

In the context of the European Competition Network (ECN), the European Commission coordinated the investigations launched by the French, Italian and Swedish competition authorities against HRS, which were jointly appointed by the ECN to lead the European national proceedings regarding MFCs.¹⁷³⁸ Booking.com offered to these three competition authorities a package of commitments for the entire European Economic Area. Following Booking.com's commitment, Expedia also announced that it would waive its rate availability and MFC clauses in contracts with hotels in Europe for the next five years.

1738 European Commission, Press Release, Antitrust: Commission announces the launch of market tests in investigations in the online hotel booking sector by the French, Swedish and Italian competition authorities available at europa.eu/rapid/press-release_IP-14-2661_en.htm (December 15, 2014).

The commitments remove the MFC clauses from its contracts with hotels that concern parity with third party booking services, as well as those requiring parity with hotel's direct sales. Hotels may consequently freely apply lower prices and/or better commercial conditions on platforms in competition with Booking.com and allocate them larger quotas of rooms. They may also offer prices at a lower rate than those displayed on the Booking.com website via their offline sales channels (on-site bookings, by telephone, fax, email, instant messaging, physical sales). Lower discounts than those displayed on the Booking.com website may also be offered to customers who are members of loyalty programmes, thus substantially increasing the hotels' margin for maneuver. These commitments are undertaken for 5 years, coming into force from 1 July 2015. According to the French Competition Authority, these commitments should 'provide an impetus to competition between Booking.com and competing OTAs, allowing the commissions levied on the hotels to fall', they also provide hotels 'some countervailing power by considerably improving their commercial and pricing freedom', while maintaining 'at the same time the OTAs' [...] economic model which provides consumers with powerful research and comparison services'.¹⁷³⁹ The French Competition Authority's decision has been appealed to the Paris Court of Appeal. Investigations against Booking.com's and Expedia's MFC clauses are however still ongoing in few EEA Member States, notably in Germany. One may also note that France has also taken legislative action in this area by enacting a law on August, 6th, 2015, which declares illegal and unenforceable price parity clauses regarding contracts between hotels and OTAs, irrespective of the channel concerned, offline or online.¹⁷⁴⁰

Investigations on MFCs have also been launched against Amazon's price parity policy applicable to third party sellers trading on Amazon's 'Marketplace' retail platform, both in the UK and Germany. The price parity clauses prohibited sellers from selling products which they offer on Amazon more cheaply on any other online sales channel. Both the German Bundeskartellamt and the OFT found that these clauses rendered difficult for other internet marketplaces to compete with Amazon and for new platforms entering the market to reach a large number of customers. The MFCs were also found to soften competition between Amazon and other internet marketplace operators, leading to increased seller fees and generally higher retail prices with insufficient countervailing ben-

1739 Autorité de la Concurrence, Pres Release, Online hotel booking sector (April 21, 2015), available at www.autoritedela-concurrence.fr/user/standard.php?id_rub=607&id_article=2535, Decision 15-D-06 *concerning practices implemented in the online hotel booking sector*, available at < www.autoritedelaconcurrence.fr/user/avisdec.php?numero=15-D-06; Italian Competition Authority, Press Release, (April 21, 2015) available at www.agcm.it/en/newsroom/press-releases/2207-commitments-offered-by-bookingcom-closed-the-investigation-in-italy-france-and-sweden.html ; Swedish Competition Authority, Press Release, (April 21, 2015), available at www.konkurrensverket.se/en/news/commitments-given-by-booking-com-benefit-consumers/ (regarding Booking.com's commitments). See also Swedish Competition Authority, Press Release (October 5th, 2015), available at www.konkurrensverket.se/en/news/investigation-of-the-online-travel-agency-expedia-closed/ (regarding Expedia's commitments). Other NCAs published press releases announcing their approval of the proposed pan-European solution, refraining from launching their own investigation (Netherlands, Denmark, Greece, Ireland, Austria etc).

1740 Article 133 of Loi No, 2015-990 pour la croissance, l'activité et l'égalité des chances économiques, August 6th, 2015, available (in French) at www.legifrance.gouv.fr/eli/loi/2015/8/6/2015-990/jo/texte.

efits, to the detriment of consumers. The German Bundeskartellamt considered that the price parity clauses were a horizontal, price-related agreement between competitors as Amazon and the third party sellers using its Marketplace compete to sell their products to the same group of customers on the same level of trade. This was found to affect the pricing policy of the third party sellers on the Marketplace as well as on their own homepages (wide-retail MFC). Amazon abandoned the price parity clauses for its Marketplace across the EU in 2013, and changed its general terms and conditions for some of the sellers. In order to convince the UK and German competition authorities that contractual conditions would change for all sellers, and that Amazon would not revert to its previous business practices, Amazon took several further measures to reassure the authorities to close formally their respective cases.

The European Commission also opened an investigation against Amazon's price parity policies in the distribution of e-books.¹⁷⁴¹ The Commission was concerned about clauses included in Amazon's contracts with publishers, requiring the publishers to inform Amazon about more favourable or alternative terms offered to Amazon's competitors and/or offer Amazon similar terms and conditions than to its competitors, or through other means ensure that Amazon is offered terms at least as good as those for its competitors. These clauses may shield Amazon from competition from other e-book distributors, limiting intra-brand competition to the detriment of consumers. This is not the first time that the Commission dealt with MFC clauses in e-books, as it had the chance to examine conduct involving Apple's agreements with five major publishers in the *e-books* investigation. The final commitments included, as regards the four publishers, a price MFC ban and, as regards Apple, a retail price MFC ban.¹⁷⁴²

One should finally note the CMA's recent report on Private Motor Insurance, the final report being published in September 2014, which summarises well the state of the law in the UK.¹⁷⁴³ The report addresses the lawfulness of MFCs included in agreements between private motor insurance providers and care insurance price comparison websites (PCW), whereby they agree that the private insurance policy offered by the insurer through the PCW will not be sold at a lower price on other PCWs. PCWs are not wholesalers of insurance but intermediaries, 'matching' two sets of customers (PMI providers and retail consumers), aiming to attract both sides to their platforms. The retail price to consumers is set by the PMI providers (agency model of retail MFC). The CMA further observed that competition is occurring at both sides of the platform and that PCWs appeared to enjoy a significant degree of market power against PMI providers as their consumers mostly practices 'single-homing', that is a consumer uses a single PCW to compare policy prices and does not compare prices across several PCWs for a given transaction. It was noted in the final report that PCWs have become an increasingly important sales channel for PMI, accounting for 55–65% of all new business sales. The CMA distinguished between narrow MFC, where an insurer and a PCW agreed that the

insurer would not offer the same policy at a lower price on its own website as it offered through the PWC, which the CMA considered were unlikely to give rise to anti-competitive effects and which it found necessary to ensure the viability of PCW's by preventing free riding on PCW's retail services and protecting their reputation as a low-cost supplier, and wide-MFC, which are likely to have an anti-competitive effect both in the PMI and the PCW markets. Indeed, a wide-MFC closes any possibility the customer has to purchase the same PMI policy more cheaply from another PMI provider. The CMA considered that wide-MFCs softened competition between PCWs, reduce the incentives for incumbents and entrants to innovate and lead to an increase of commission fees and policy premiums.¹⁷⁴⁴ The CMA also concluded that wide-MFCs were not necessary, as in their absence, there was little danger of free-riding from other PCWs. The CMA prohibited wide-MFCs for imposing a significant detriment to consumers, as well as any other equivalent behaviours, for example threatening to delist a PMI provider if it offered PMI policies more cheaply on other PCW.

Brazil: There is one case worth mentioning that involves APPAs in Brazil. The proceedings initiated after a complaint filed by the Brazil Hotel Operators Forum ("FOHB"), arguing that the online travel agencies (OTAs) were perpetrating anticompetitive conducts in the market for online booking services for hotels, due to the imposition of MFN clauses (also known as wide price parity clauses) to hotels that wished to be listed on the Respondents' websites.

Brazil's competition authority, CADE, considered that the imposition of price parity clauses was sufficient to reduce the incentives for competition between OTAs and increase barriers to entry. CADE obtained commitments¹⁷⁴⁵ from Decolar.com, Expedia.com and Booking.com, the three largest OTAs in Brazil, settled with CADE.¹⁷⁴⁶ According to the commitments, the OTAs agreed to stop using wide price parity clauses, refraining from imposing to their suppliers of accommodation obligations regarding price parity to other OTAs and to off-line booking channels. However, CADE accepted narrow price parity clauses, allowing harmonisation of prices in limited situations: (i) in relation to general offers in the hotel website; (ii) in relation to direct hotel offers in meta-search websites and (iii) offline reservations that are publicised online. CADE also recognised that OTAs are a new digital phenomenon and, therefore, the authority still had limited experience. In this context, CADE's prohibition of wide parity clauses was limited to a period of three years, during which the authority will monitor the players' practices and the market's technological development.

India: While there isn't much litigation on APPA in India, the CCI's post-investigation order in *M/s Jasper Infotech Private Limited (Snapdeal) Vs. M/s Kaff Appliances (India) Pvt. Ltd.*, delivered in January 2019¹⁷⁴⁷ contains a statement that encapsulates the CCI's position on the issue. The CCI observes: "Almost all the evolved competition authorities have

considered restraints imposed by or on the online platforms as vertical restraints e.g. cases pertaining to Most Favored Nation (MFN) clauses, Across Price Parity Agreements (APPA), non-price restrictive clauses etc.”¹⁷⁴⁸ In this case the platform owner had alleged RPM (dealt under anti-competitive agreements) on part of a supplier on its platform.

The Commission further observes that “[i]n India, however, the alleged RPM is assessed under rule of reason analysis i.e. only if such conduct/agreement/understanding causes or is likely to cause an AAEC [appreciable adverse effect on competition], that the same falls foul of Section 3(4)(e) read with Section 3(1) of the Act. This is in sync with the existing economic literature which suggests that vertical agreements deserve a rule of reason analysis, simply owing to the fact that the vertical agreements are concluded between entities operating at different levels in the production chain who generally produce complementary products or services and are not as such placed in a competitive relationship. To safeguard their respective interests, such entities necessarily enter into number of commercial agreements, many of which may not necessarily be anti-competitive and rather may be efficiency enhancing with sound economic justifications. Since these parties are not producing substitutes as such and thus not competing as such, their incentives are generally aligned to that of end consumer. In such a scenario, it becomes imperative that the competition authorities which are mandated to proscribe anti-competitive agreements, do not end up restraining pro-competitive commercial agreements/arrangements.”¹⁷⁴⁹

The CCI continued explaining that in order to establish a contravention under Section 3(4) read with Section 3(1) of the Act, two conditions need to be fulfilled – firstly, that the agreement/arrangement/ understanding ought to exist and, secondly, that such agreement/arrangement/ understanding has caused or has the potential to cause AAEC”,¹⁷⁵⁰.

In the end, the CCI rejected the claim as there was insufficient evidence on the record of price restriction or minimum RPM. Furthermore, the Commission also found that there was sufficient intra-brand competition, and hence no AAEC.

6.3.4. Online RPM or RPM facilitating conduct

Competition authorities are increasingly concerned by RPM in online markets (iRPM), in particular in view of the interaction between RPM and parity clauses (APPAs), as well as conduct facilitating RPM, such as internet minimum advertised price restraints (iMAP) and dual pricing.¹⁷⁵¹ There are various ways in which vertical restraints may be used to facilitate RPM conduct. The EU Vertical restraints guidelines list vertical restraints that

¹⁷⁴⁸ P17, Ibid

¹⁷⁵⁰ P 20, ibid

¹⁷⁵¹ Recently, the European Commission has announced the launch of an investigation of a potential restriction on the ability of online retailers to set their own prices for widely used consumer electronics products such as household appliances, notebooks and hi-fi products accompanied by the use of pricing software that automatically adapts retail prices to those of leading competitors. See European Commission, Press Release IP/17/201 (February 2017), available at europa.eu/rapid/press-release_IP-17-201_en.htm.

may be used to indirectly facilitate RPM: fixing the retail margin, fixing the maximum discount a retailer can offer from a prescribed price level, making the grant of rebates or reimbursement of promotional costs conditional on the maintenance of a particular price level, and linking the prescribed resale price to competitors' resale prices (retail APPAs/MFCs).¹⁷⁵² In addition, 'threats, intimidation, warning, penalties, delays or suspension of deliveries if a given price level is not observed' can also induce a retailer to maintain a particular resale price.¹⁷⁵³ Such indirect price fixing can be made more effective in facilitating RPM if there are also monitoring mechanisms in place that help to identify price-cutting distributors. Measures that reduce a retailer's incentives to discount prices, such as the supplier printing a recommended resale price on a product or the supplier obliging the buyer to apply an MFC clause can also enhance the effectiveness of indirect uses of vertical restraints as a way of facilitating RPM.¹⁷⁵⁴ According to the Commission, 'the same indirect means and the same "supportive" measures can be used to make maximum or recommended prices work as RPM'.¹⁷⁵⁵ The horizontal effect of these facilitating practices may be more pronounced in an online environment, because of the higher transparency and the information dissemination in the online economy. However, one needs to be cautious and not rush in conclusions that a facilitating practice constitutes an RPM. As the Commission notes, 'the use of a particular supportive measure or the provision of a list of recommended prices or maximum prices by the supplier to the buyer is not considered in itself as leading to RPM'.¹⁷⁵⁶

The consumer harm narratives for online RPM and online RPM facilitating conduct are similar than those for traditional RPM: they limit the retailer's ability to set retail prices, thus reducing the intensity of intra-brand competition, they facilitate collusion, or exclude rivals at the supplier or retail level, but also dampen interbrand competition. For instance, a iMAP may reduce intra-brand competition between online and offline sellers in circumstances where an online retailer cannot engage in customer negotiations as readily as offline retailers¹⁷⁵⁷. Exclusion at the supplier level may arise if the conduct guarantees a retail margin that makes a retailer less willing to stock a rival supplier's product. Foreclosure of downstream distribution channels in this manner may reduce inter-brand competition between suppliers. Exclusion at the retail level may also occur if a supplier is induced to adopt an indirect price maintenance scheme that reduces discounting retailers' ability to compete. Offline retailers may have an incentive to try to induce suppliers to implement MAP policies, refuse to supply or otherwise discriminate against discounting online retailers.¹⁷⁵⁸ At the same time, the Internet 'greatly lowers the cost of disseminating 'catalogs' to those consumers who are likely to buy particular products', thus may be providing more incentives for manufacturers, but also compet-

ing retailers, to initiate RPMs.¹⁷⁵⁹ Furthermore, ‘the ease of price comparison on the Internet increases the free rider problem, making RPM a desirable tool for some manufacturers seeking to control their brand image and protect their distribution networks’, but it also ‘makes it easier to enforce retail cartels because it makes price-cutting more obvious’ and increases the “risk of horizontal effects from RPM when a manufacturer vertically integrates online, leading to its setting the price for its competitors’.¹⁷⁶⁰

The OFT (CMA’s predecessor) examined iMAP policies in the mobility scooters case where it found that a manufacturer and several retailers of Roma-branded mobility scooters had infringed Chapter I CA 98 by entering into vertical agreements prohibiting some retailers from advertising prices online for certain mobility scooters and prohibiting online sales by certain retailers.¹⁷⁶¹ In a separate investigation in the same sector, the OFT found that a manufacturer and several retailers of certain Pride-branded mobility scooters had infringed the CA 98 by entering into vertical agreements that prohibited the advertising of prices below the Recommended Retail Price (RRP) set by Pride.¹⁷⁶² The OFT considered that the use of iMAPs can soften intra-brand competition, reduce discounting and raise prices to consumers. In addition, the use of iMAPs may reduce price transparency and significantly increased consumers’ search costs. This was of particular concern in this case as consumers of mobility scooters typically incur high search costs due to their particular circumstances and are therefore less able to shop around by physically visiting various retail premises. The OFT was particularly concerned that a prohibition on price advertising and a prohibition on online sales, in the context of a selective distribution system (where intra-brand competition was already weak) undermined the benefits brought about by the internet. According to the OFT, ‘having the freedom to advertise retail prices on the internet can intensify price competition between retailers and enable consumers to obtain better value for money’. The prohibitions were also liable to disproportionately impact on potentially more vulnerable consumers that are often first-time buyers and place them at a particular disadvantage. The OFT also considered the differential between Pride’s RRP and retailers’ actual selling prices., in particular where they did not comply with Pride’s requests and/or instructions and/or did not fully respect the agreement, and found that the online prices advertised for certain Pride mobility scooters were significantly below Pride’s RRP.

In 2016, the CMA found that 2 businesses, one supplying commercial catering equipment and the other supplying bathroom fittings, had broken competition law by engag-

ing in resale price maintenance (RPM). In the *Commercial Catering Equipment* case, the supplier had imposed a 'minimum advertised price' (MAP) policy that restricted the price at which retailers could advertise the supplier's product online¹⁷⁶³. It seems that the MAP Policy was introduced in response to low prices by online resellers putting pressure on the prices and margins of the supplier's traditional resellers. The supplier enforced this MAP policy by threatening to charge dealers higher cost prices for products, or stopping supply altogether, if they advertised below the minimum price. These warnings of sanctions were credible, as the supplier did withhold or cease supply, both temporarily and permanently, to resellers that did not comply with the MAP Policy, henceforth effectively incentivizing the resellers to comply with the MAP Policy. The CMA noted that restrictions on advertising prices below a certain level have been found to lead to *de facto* RPM and constituted a restriction by object of competition law, falling under the prohibitions of both Chapter I CA98 and Art. 101(1) TFEU¹⁷⁶⁴. It also noted that agreements and/or concerted practices, which have as their object the restriction of competition, are very unlikely to benefit from individual exemption and did not explore any efficiency gains in the context of Art. 101(3) TFEU and the UK equivalent.

In the *Bathroom Fittings* case, the manufacturer had threatened retailers with penalties for not pricing at or above a 'recommended' online price as set out in 'online trading guidelines'¹⁷⁶⁵. Enforcement threats included charging retailers higher prices for products, withdrawing rights to use the supplier's images online or withholding supply of products. The CMA found in light of this legal and economic context that the Recommended Online Price was not simply a recommendation but fixed a minimum resale price in respect of online sales, and it formed part of an agreement qualified as an RPM, having as its object to prevent, restrict or distort competition and being, by its very nature, harmful to the proper functioning of normal competition¹⁷⁶⁶. Again, the CMA found that the agreement could not be exempted.

Dual pricing restrictions, that is when there are dissimilar supply conditions from a producer to on-line retailers compared to retailers using traditional channels of distribution, have also been the focus of several NCAs' investigations and proceedings in national courts, sometimes with conflicting approaches. Dual pricing restrictions may take various forms: one is to set higher wholesale prices for internet retailers, either directly or indirectly through reward/loyalty programmes; another one is to offer online customers warranties or a level of service different from what they would have otherwise obtained. According to the European Commission's vertical restraints guidelines, any obligation that dissuades distributors from using the Internet, such as the require-

ment that a distributor pays a higher purchase price for units sold on-line ('dual pricing'), is considered as a hardcore restriction under the VBER.¹⁷⁶⁷ However, according to the Commission, 'in some specific circumstances, such an agreement may fulfil the conditions of Article 101(3)', in particular 'where a manufacturer agrees such dual pricing with its distributors, because selling online leads to substantially higher costs for the manufacturer than offline sales'. For instance, this may be the case 'where offline sales include home installation by the distributor but online sales do not', as the latter may lead to more customer complaints and warranty claims for the manufacturer.¹⁷⁶⁸

In 2009, the Dutch Authority for Consumers and Markets (ACM) decided that dual pricing should not be prohibited in the absence of a dominant position.¹⁷⁶⁹ Furthermore, Dutch courts have ruled that the Block Exemption Regulation covers the issuance of dissimilar supply conditions from a producer to on-line retailers compared to retailers using traditional channels of distribution, but have also noted that this approval is conditional to the existence of an added value differential between the two channels, in this case the value differential being the display of the products, the personal advice given by trained personnel, and the installation of the equipment.¹⁷⁷⁰ To the extent that the offline distribution channel yields greater value, the supplier has a proper incentive to apply better conditions to traditional shops so as to encourage sales through this channel and to employ dual pricing in order to increase the retail margin for brick and mortar stores.

The German competition authority took a more restrictive position to dual pricing.¹⁷⁷¹ In 2013, the BKartA initiated proceedings against Bosch after some dealers alleged that Bosch applied a rebate system which put dealers who sold household appliances in both physical and online stores (omni-channel retailing) at a disadvantage as an increase in turnover generated online led to a decrease in the total rebates received.¹⁷⁷² The rebate

1767 Vertical restraints guidelines, paras 52(d) and 64. This 'does not exclude the supplier agreeing with the buyer a fixed fee (that is, not a variable fee where the sum increases with the realised offline turnover as this would amount indirectly to dual pricing) to support the latter's offline or online sales'.

1771 See also the restrictive position of the German Bundeskartellamt (BKartA) concerning dual pricing practices in a document published in 2013 on 'Vertikale Beschränkungen in der Internet Ökonomie' (Vertical Restrictions in the Internet Economy), available (in German) at www.bundeskartellamt.de/SharedDocs/Publikation/DE/Diskussions_Hintergrundpapier/Bundeskartellamt%20-%20Vertikale%20Beschr%C3%A4nkungen%20in%20der%20Internet%C3%B6konomie.pdf?__blob=publicationFile&v=2.

1772 This was part of proceedings opened against three German companies employing dual pricing restrictions: Gardena (gardening tools), Dornbracht (sanitary ware) and Bosch Siemens Hausgeräte (household appliances).

system therefore created incentives for dealers to limit their online sales and as a result, competition through online sales was reduced. The BKartA considered the rebate system to be anticompetitive dual pricing, constituting a restriction of competition by object according to Article 101 TFEU and the equivalent provision in German competition law. It also found that dual pricing does not entail any efficiency benefits and that, in any case, there were less drastic ways of covering the higher costs of offline sales. Bosch informed the BKartA that it would put in place a new rebates system according to which similar rebates can be obtained for sales in offline shops and for online sales.

The French competition authority examined this issue in its Opinion No 12-A-20 of 18 September 2012 on e-commerce where it seems to accept that the existence of a difference in remuneration for the same brick & mortar distributor depending on whether the sale occurs in a physical store or online constitutes a hardcore restriction according to the VBER but may nevertheless be justified with respect to an individual exemption under Article 101(3) TFEU or the equivalent provision of national competition law.¹⁷⁷³ In particular, the French competition authority accepts that, when a distribution service can only be provided in store, it may be justifiable for its remuneration to be based on the turnover realised exclusively in the store(s). Yet, such restrictions may not unjustifiably reduce the competitive pressure exerted by on-line retailers on traditional retailers.

The OFT had also examined dual pricing clauses in its investigation in 2006 against the discount scheme offered by Yamaha.¹⁷⁷⁴ Yamaha offered discounts to distributors specifically rewarding face-to-face sales of high-end electronic pianos and keyboards, the level of the discounts depending on the ratio of face-to-face sales v distance sales (including Internet sales). The OFT found that the discount scheme restricted Internet sales and that it acted as a price stabilizing measure targeted at retail discounters. Yamaha took the decision to withdraw the scheme and the OFT closed the investigation.

The Commission's E-commerce final report, paragraph 35 explained that "dual pricing is often viewed by stakeholders as a potentially efficient tool to address free-riding. They argue that dual pricing may help to create a level playing field between online and offline sales, taking into consideration differences in the costs of investments. Comments in relation to dual pricing point to the need for a more flexible approach to performance-related wholesale pricing. A more flexible approach would allow for differentiation between sales channels, depending on the actual sales efforts, and would encourage hybrid retailers to support investments in more costly (typically offline), value added services".

Following in the footsteps of the E-commerce inquiry, the European Commission opened an investigation in February 2017 against Asus, Denon & Marantz, Philips and Pioneer for engaging in RPM on electronics products. In July of 2018, the Commission issued a deci-

1773 Autorité de la concurrence, Avis du 18 septembre 2012 relatif au fonctionnement concurrentiel du commerce électronique, summary (in English) available at www.autoritedelaconcurrence.fr/user/standard.php?id_rub=418&id_article=1969.

sion finding an illegal RPM based on merely recommended retail prices, but enforced through algorithmic price monitoring and subsequent requests to increase prices¹⁷⁷⁵. The Commission imposed a total of €111 million in fines on those four undertakings. A few months later, the Commission imposed a fine of €40 million on clothing producer Guess for several vertical restraints, one of which concerning RPM¹⁷⁷⁶.

U.S. courts have not heard a dual pricing case. Plaintiffs generally have difficulty prevailing in cases challenging vertical restraints. Under the Sherman Act, they even have difficulty challenging resale price maintenance (RPM), although many states still prohibit the practice, viewing it as per se illegal.¹⁷⁷⁷ At the federal level, the U.S. Supreme Court in *Dr. Miles Med. Co. v. John D. Park & Sons Co.*,¹⁷⁷⁸ initially held the same view. After *Leegin* in 2007, however, all federal courts review RPM claims under the rule of reason.¹⁷⁷⁹

In terms of vertical restraints on the Internet, U.S. courts have decided a few internet minimum advertised price (IMAP) cases. The framework for finding liability in those cases depended on classifying the practice as RPM. While reserving the possibility of an appellate court constructing a different framework, the rule of reason probably will continue to govern IMAP claims.¹⁷⁸⁰ In addition to establishing that the IMAP at issue resembles RPM, a plaintiff must show that the IMAP produces anticompetitive effects.¹⁷⁸¹

Considering the elements in reverse order, an IMAP could prevent many transactions. Proving the fact would require proving a hypothetical, which could involve collecting significant data from the platform and perhaps third parties.¹⁷⁸²

Relating to whether IMAPs operate similar enough to RPM, district courts have filed conflicting views. The Western District of New York has held that they do not, stating that the freedom to sell at any price, notwithstanding a restraint on the minimum price that a dealer may advertise, distinguishes IMAPs from RPM.¹⁷⁸³ By contrast, the Eastern District of New York has viewed the two practices as conceptually similar, because both restrict the retail prices of Internet retailers, even if IMAPs purport to control only advertised prices.¹⁷⁸⁴

The issue of whether a contract exists can determine whether Section 1 or Section 2 of the Sherman Act applies. Absent a contract, a plaintiff must prove market power upstream, and perhaps downstream, under Section 2. The Colgate doctrine then could prevent liability, since a seller may choose retailers with which to deal after suggesting a minimum advertising price.¹⁷⁸⁵

Under a Section 1 rule of reason analysis, courts are free to consider the intent and options of suppliers. Instead of an IMAP, a supplier could raise its wholesale price across the market. It may choose this course to prevent the margins of retailers and prices at the retail level from falling after retail competition has intensified in a market.¹⁷⁸⁶ If suppliers can discriminate in their prices to retailers, a supplier may lower its price to a retailer that has attained market power, to maintain the quantity of goods sold.¹⁷⁸⁷

Suppliers may implement an IMAP to manipulate a platform. When suppliers have attained greater market power, platforms often respond by lowering its fees to consumers and sellers to encourage more activity or entry on each side of the platform.¹⁷⁸⁸

When IMAPs function as maximum RPM where retailers set prices too high, they can address double marginalization. This claim has plausibility, since most retailers will not exceed an IMAP due to price transparency on the Internet.¹⁷⁸⁹

The possible pro- and anticompetitive effects of IMAP practices suggest that plaintiffs will have difficulty proving an antitrust violation under the rule of reason.

Brazil: The law lists ‘to impose on the trade of goods or services to distributors, retailers and representatives, any resale prices, discounts, payment terms, minimum or maximum quantities, profit margin or any other market conditions related to their business with third parties’ as one of the possible anticompetitive conducts. Resolution 20/99, in turn, also includes a specific definition of resale price maintenance (RPM), meaning the manufacturer establishing, in an agreement, the price (minimum, maximum or fixed) to be adopted by distributors or dealers. Said Resolution consolidates the understanding that fixing minimum prices often results in anticompetitive effects, usually related to easier collusive price practices and increases the manufacturer market power, deterring the entry of more competitive distribution and reducing intra-brand competition. CADE precedents show that the practices considered legal are usually those related to suggestion of resale prices. On the other hand, minimum resale prices, especially when associated with monitoring and punishment measures, tend to raise relevant concerns from CADE’s perspective. The legality of MAPs was discussed in a recent consultation pre-

sented to CADE by Continental. Continental intended to implement an MAP to its retail distributors in the aftermarket tyres segment, aiming to preserve its business model. After recognizing the ambiguous effects generated by the MAP to consumer welfare, CADE concluded that the policy to be implemented by Continental was legal, considering: the absence of market power; the fact that the MAP was unilaterally designed by Continental; and the absence of any type of discrimination between Continental's distributors.

Russia: In Russia, Article 11 (2) of the Federal law dated 26 July 2006 № 135-FZ "On Protection on Competition" prohibits vertical agreements that 'result or may result in the maintenance of the resale price of goods, unless the seller sets the maximum resale price (RPM); or vertical agreements that set forth the buyer's obligation not to sell the goods of the seller's competitor (exclusivity). These vertical agreements are *per se* prohibited unless they are considered acceptable based on the Article 12 of the Federal law "On Protection on Competition" (commercial concession agreements; vertical agreements between the undertakings whose market shares on the product market forming the object of the agreement do not exceed 20%; their aggregated turnover does not exceed the specific threshold).

The FAS has reviewed some cases related to coordination of the prices of online distributors/resellers. Thus, in its decision dated 27 March 2017 in the *Apple* case¹⁷⁹⁰ the FAS established that Apple Rus was engaged in practices aimed at maintaining the uniform level of prices for the certain models of Apple smartphones in the Russian Federation. This included publishing press-releases with recommended prices of Apple smartphones that were available to Apple's distributors and resellers. As such, one may doubt that the practice could indeed be sufficient to trigger a competition law violation. However, this must be understood in a broader context, where Apple Rus imposed control over the prices actually set by its resellers and distributors through e-mail communication, 'reports' with competitors' prices sent by resellers, as well as through specific contract clauses (allowing Apple Rus to suspend or cancel orders without explanation). This constitutes an effective mechanism of maintaining the prices at the uniform level 'recommended' by Apple, in line with the approach to RPMs adopted in the *EU Vertical Restraints Guidelines*.

However, the FAS did not find the existence of a vertical restraint in this case, and qualified the violation as coordination of economic activity that affects competition (Article 11(5) of the Federal law "On Protection on Competition"). This is related to a restrictive interpretation of the concept of 'vertical agreements' by the FAS of Russia. In accordance with the Clarification of the Presidium of the FAS of Russia N.2 dated 17 February 2016, "vertical" agreements are implemented through civil contracts providing the transfer of goods from one person to another (sale agreement, supply agreement, distribution agreements, etc.). Civil contracts or agreements that do not provide for the transfer of goods from one person to another cannot be considered as "vertical" agreements". Therefore, the lack of formal supply/distribution contracts between Apple and some of

1790 Decision of the Federal Antimonopoly Service of the Russian Federation dated 27 March 2017 № 1-11-59/00-22-16 <https://solutions.fas.gov.ru/ca/upravlenie-po-borbe-s-kartelyami/ats-20961-17>.

resellers (who bought smartphones from Apples distributors and not from Apple directly) was the reason why such practices could not be qualified as vertical restraints.¹⁷⁹¹ A similar case in 2018 concerned LG Electronics.¹⁷⁹² It refers to exactly the same practices of LG Electronics Rus regarding maintenance of the prices for LG smartphones in Russia. Again, the FAS qualified LG practices as coordination of economic activity, and not as vertical restraints, due to the lack of formal contractual relationships.

The case-law described above demonstrates that the approach of the FAS to RPM practices is quite formalistic, as it hinges upon the concept of ‘transfer of good’. However, Article 11 of the Federal law “On Protection on Competition” still allows such practices to be qualified as anti-competitive coordination, provided that the seller and the buyers are not active at the same market.

India: In *Ashish Ahuja vs. Snapdeal*, the CCI looked into the issue of resale price maintenance. In this case, complainant is engaged in selling various computer and mobile accessories, whereas opposite party (Snapdeal) is a popular online market place, wherein different players sell their products for which the web portal charges a commission.

The Complainant used to sell its product via the e-portal of the opposite party. Subsequently, the Complainant was removed from the e-portal and was not allowed to sell its product. The reason for Snapdeal to take such a step was that the manufacturer (ScanDisk) insisted that the storage device (relevant product) sold through the e-portal should be bought from its authorised dealer to avail after-sale service warranties. The complainant alleged that by this practice, Snapdeal and ScanDisk are indulging in RPM, curtailing the freedom of sellers to offer better price for consumers.

The CCI did not find fault in such insistence upon ScanDisk and subsequent measure taken by Snapdeal. The CCI observed that ScanDisk is within its rights to protect the sanctity of distribution channel and that vide its circular, ScanDisk had only clarified that the full range of all India after sales and warranty services offered by it is limited to those products brought from its authorised national distributors. The CCI stated “In a quality-driven market, brand image and goodwill are important concerns and it appears a prudent business policy that sale of products emanating from unknown/unverified/unauthorised sources are not encouraged/allowed”.

However, in another case, *M/s Jasper Infotech Private Limited (Snapdeal) Vs. M/s Kaff Appliances (India) Pvt. Ltd.*, with similar facts as above, the CCI had a *prima facie* opinion that Kaff was involved in RPM and ordered an inquiry. In this case, Kaff Appliances had written to Snapdeal that it would not extend warranties to the products sold by unauthorised dealers or distributors.

Unlike ScanDisk in the earlier case, here Kaff Appliances had clearly mentioned, “If MOP [Market Operating Price] of its products is not maintained then they will not allow Snap-

1791 See FAS decision dated 27 March 2017 № 1-11-59/00-22-16, <https://solutions.fas.gov.ru/ca/upravlenie-po-borbe-s-kartelyami/ats-20961-17>.

1792 Decision of the Federal Antimonopoly Service of the Russian Federation dated 02 March 2018 № 1-11-18/00-22-17 <https://solutions.fas.gov.ru/ca/upravlenie-po-borbe-s-kartelyami/ats-14552-18>.

deal to sell its products either by authorised or unauthorised dealers or distributors". This had lead the CCI to conclude that there is a prima facie case of RPM under the Competition Act and ordered further investigation.

It might be noted that in *Ashish Ahuja vs. Snapdeal* also the discounted price offered by the Complainant was the core issue that triggered the manufacturer (ScanDisk) to issue a circular. However, there was no direct mention of MOP in the circular. Moreover, had there been an investigation, more information would have come up that could have tilted the CCI's conclusion.

Be that as it may, the product involved in this case seems to have been obtained through 'parallel import'. It should be noted that parallel import is pro-competitive, and the issue should have been raised before the CCI. One of clauses of the above-said ScanDisk circular was: "All third party importers apart from the above-named four authorised national distributors are parallel importers and ScanDisk Corporation does not authorise, endorse or support parallel importation". While different countries have different regimes with respect to parallel imports, India follows international exhaustion of Intellectual Property (IP) rights with the exception of copyright. Hence, the part of the circular that contravenes or does not go along with the Indian law can be deemed invalid. This issue however was not raised by the Complainant or by the CCI *suo motu*.

6.3.5. Dual distribution and dual role (platform/retail) of online platforms

'Dual distribution' exists when the manufacturer simultaneously sells to independent dealers and is also present at the distribution level of the commercialization process by supplying customers directly. This is increasingly the case with e-Commerce where some digital platforms exercise a dual role as marketplace and online retailer. For instance, Amazon Marketplace offers merchants a wide range of functionalities. They can use the Amazon Marketplace as a new or additional sales channel, building on Amazon's brand. They can also purchase additional Amazon services such as warehousing their products in Amazon's fulfillment centers, where Amazon handles the packing and shipment of the goods and provides customer service for the merchants. In addition, Amazon collects and transfers shopper payments to the merchants. At the same time, Amazon is one of the largest online retailers itself. Depending on the product, Amazon's own retail offerings may directly compete with those of the merchants using the Amazon Marketplace. Due to the comparable platform and similar shopping experience, many shoppers may not recognize any difference between Amazon's own retail services and its marketplace activities for other merchants.

Dual distribution may take different forms: the manufacturer may operate its own distribution network in competition with other retailers or he may choose to establish an independent exclusive distribution system but will preserve certain territories for his own distribution outlets. To the vertical relation that usually links the manufacturer with independent dealers, dual distribution adds a horizontal layer, as the manufacturer competes with the dealers of his network (intrabrand downstream competition) and

with all other dealers in the relevant market (interbrand downstream competition). Unlike the conventional horizontal competition between suppliers, 'the dual distributing manufacturer creates competition with himself by supplying a dealer'¹⁷⁹³.

This hybrid relationship has confused competition law authorities and courts, as it is difficult to decide which, horizontal or vertical, dimension should prevail in order to characterize the agreement as being vertical or horizontal. For example, the supplier's suggestion of a resale price and the retailer's acceptance of that suggestion may be qualified as horizontal price fixing, as the supplier and the retailer are also in direct horizontal competition. There are a number of pro-competitive justifications for dual distribution practices. First, they offer an opportunity for the manufacturer to monitor the performance of his retailers. By being present at the distribution level the manufacturer will be able to collect information on the optimal level and quality of distribution services for the final consumers and will thus take this information into account in order to fine tune his decision to impose vertical restrictions that will provide adequate competitive incentives at the retail level¹⁷⁹⁴. Second, the manufacturer will be able to prevent free riding, encourage the provision of presale services, protect his reputation, and avoid opportunistic behaviour by the dealers. Third, dual distribution also increases the opportunities to serve different types of customers, in particular those that the manufacturer's regular dealers do not serve. Fourth, the manufacturer may engage in price discrimination, which in some cases may be beneficial to consumers, in particular if imperfect price discrimination to low value buyers has the effect to increase output. De facto discrimination could, however, also be achieved without employing a dual distribution practice. It would be possible to impose intrabrand restraints on independent dealers and maximum resale prices or to charge all dealers the same price and provide a rebate on re-sales to specific categories of consumers.

There is no reason to examine dual distribution differently from other vertical restraints, as the same effects may be similarly achieved by more conventional vertical distribution practices. Dual distribution will not generally increase manufacturer's market power. Herbert Hovenkamp observes that: (a) manufacturer who has no market power cannot use dual distribution to create it. Furthermore, even a monopoly manufacturer generally cannot increase its market power by insulating its wholly-owned retail outlets, even if the effect is to injure competing, independent retailers. If the manufacturer has market power, any monopoly profits earned at the retailer level could also be earned at the manufacturer level¹⁷⁹⁵. The horizontal dimension of dual distribution may also be a source of anticompetitive effects, in particular horizontal collusion. Nevertheless, collusion at the retail level will not be in the interest of the manufacturer, the latter preferring to limit any possibility of double marginalization and having no interest to participate in a cartel seeking to create market power at the retail level. Most often the reason that

1793 P. E. Areeda, *Antitrust Law Volume VIII*, ¶1606, 91 (Little, Brown & Company, 1989).

1794 See: Y Yehezkel, 'Downstream Competition Between an Upstream Supplier and an Independent Downstream Firm' Working Paper (March 2003) accessed 10 April 2008.

1795 H Hovenkamp, *Federal Antitrust Policy: The Law of Competition and its Practice* (3rd edn, 2005) 49.

manufacturers enter the distribution level is to combat collusion at the retail level¹⁷⁹⁶. A restriction of intrabrand downstream competition may affect the distribution of profits between the supplier and the retailers but ‘will not affect output to consumers since both suppliers and dealers have a considerable interest in achieving a level of output that maximizes their joint profit level’¹⁷⁹⁷. If one follows this approach, dual distribution agreements should not be treated differently from vertical restraints. Steiner’s analysis may nevertheless shed light into a less anticipated anti-competitive concern raised by dual distribution practices. As it has been previously suggested, competition authorities and courts should adopt a dual stage approach and should examine the effect of vertical restraints on both horizontal and vertical competition. Traditional analysis has focused on horizontal competition at the supplier and the retailer levels and has ignored vertical competition between the supplier and the retailers over the sharing of the profits of the vertical structure. If one takes into account this dimension of competition, the manufacturer may have the incentive to limit vertical competition by imposing price or nonprice restraints on the retailers of his network competing with him at the retail level. His incentive will be to limit the retail gross margin and to increase his vertical market share or profits upstream to the detriment of independent retailers. This may harm consumers if the manufacturer’s product benefits from an important brand loyalty. These restraints will be particularly harmful if a high percentage of the manufacturer’s brands sales are made by manufacturer-owned retail outlets or if the manufacturer imposes a vertical restraint to dealers that sell both his brand and competing brands and therefore reduces interbrand downstream competition¹⁷⁹⁸. The supplier may also want to eliminate competition among retailers in order to raise the profits of his retail outlet. The retail price will in this case be higher than in the absence of dual distribution¹⁷⁹⁹. The anti-competitive effects of dual distribution practices may be stronger than those of purely vertical restraints but they are in any case less harmful for consumers than purely horizontal restraints.

The dual role of Amazon as “the largest retailer and largest marketplace” has recently led to the opening of two parallel investigations by the European Commission and the Bundeskartellamt (announced on 19 September¹⁸⁰⁰ and 29 November 2018¹⁸⁰¹, respectively). Both investigations were triggered by several complaints of abuse of dominant position to the detriment of sellers active on the Amazon Marketplace, but the focus is slightly different: in the European Commission’s investigation, the investigated conduct relates to Amazon’s use of accumulated marketplace seller data to compete

1796 Ibid. See also: P M Ippolito, ‘Resale Price Maintenance—Economic Evidence from Litigation (Bureau of Economics Staff Report, Federal Trade Commission) (April 1998), 59–60 accessed 10 April 2008.

downstream as a retailer. By contrast, in the German investigation, the practice under scrutiny is the use of abusive terms of business and related practices, including provisions limiting liability to the disadvantage of sellers, the choice of law and jurisdiction clauses, the rules on product reviews, the non-transparent termination and blocking of sellers' accounts, the withholding or delaying payment, and clauses assigning rights to use the information material which a seller has to provide with regard to the products offered and terms of business on pan-European despatch. It is also important to note that the German competition authority mentions that such conduct is relevant not only on grounds of Amazon being in a dominant position as a retailer, but also in light of the economic dependence of sellers on Amazon's marketplace: the authority is thus also concerned about the use of relative or superior market power, a form of market power that the authority is expressly entitled to pursue to the extent that small or medium-sized enterprises as suppliers or purchasers of a certain type of goods or commercial services depend on them in such a way that sufficient and reasonable possibilities of switching to other undertakings do not exist¹⁸⁰². On 17 July 2019, the Bundeskartellamt closed the investigation accepting the commitment offered by Amazon to address the competition concern¹⁸⁰³, which include the following changes to its business terms:

- No limitation of liability for products sold on its marketplace;
- Termination and suspension of sellers' accounts will only be possible upon provision of statement of reasons and following a 30 days notice period;
- No longer exclusive jurisdiction for dispute resolution in Luxemburg courts for all European marketplaces
- Right for sellers to object to unjustified returns and reimbursements obtained by customers through Amazon;
- More limited rights for Amazon to use sellers' product information, and no requirement for sellers to provide Amazon Market place with products of the same high quality as the ones used in other sales channels;
- Increased ability for sellers to make public statements about their business relations with Amazon without Amazon's written prior approval.
- More salience and traceability for the rules and regulations applicable to sellers, and right to receive 15 days' notice for any changes thereto;
- Amazon's own "Vine" rating programme, which was previously available only to suppliers of Amazon Retail, will be gradually made available to those marketplace sellers which own a brand name registered with Amazon.

1802 See Gesetz gegen Wettbewerbsbeschränkungen, § 20. See also the assessment by Friso Bostoen, 'It's raining Amazon probes: the Bundeskartellamt joins the Commission in investigating the tech giant's marketplace practices', CoRe Blog (9 Jan 2019), at <https://coreblog.lexxion.eu/its-raining-amazon-probes/>

1803 https://www.bundeskartellamt.de/SharedDocs/Meldung/EN/Pressemitteilungen/2019/17_07_2019_Amazon.html

Interestingly, the commitment adopted by Amazon with the Bundeskartellamt are of global geographical scope. This is a strategic concession, as it helped alleviate the similar concerns expressed by the Austrian competition authority, who had opened an investigation in February 2019 about the following unfair trade practices:

- abrupt termination of seller-accounts
- obligation to disclose purchase prices
- adding of incorrect delivery details by Amazon to the sellers' accounts
- unjustified loss of product rankings of sellers
- jurisdiction clauses, which complicate to take legal actions¹⁸⁰⁴.

As a result of these commitments, the Austrian competition authority issued a press release on the same day of the closing of Bundeskartellamt's investigation and of the formal opening of the investigation by the European Commission¹⁸⁰⁵, informing that it will not continue its own investigation¹⁸⁰⁶. In the meantime, however, another investigation was opened by the Italian competition authority on different grounds, namely that Amazon would grant advantages in terms of visibility and improvement of sales on Amazon.com to sellers that are registered with the "Fulfillment by Amazon" program – which involves the delegation to Amazon of the placement of orders, the stocking in Amazon's warehouses, the packaging and shipping as well as the post-sale assistance¹⁸⁰⁷. Among the considerations relied upon by the Autorita' Garante to open its investigation is the fact that the marketing for the "Fulfillment by Amazon" program explicitly mentions "price advantages", "protection from negative feedback" and "improved indexing" on its Marketplace,¹⁸⁰⁸ and that sellers can gain access to the "Buybox" option (which Amazon allocates to top sellers, and through which more than 80% of the sales take place¹⁸⁰⁹) despite the fact that the price of their product is higher than those of competitors who don't rely on the program¹⁸¹⁰. The authority reached the preliminary conclusion that this conduct amounts to an abusive self-preferencing, made possible by the dual role of Amazon, which leverages its dominant position in e-commerce marketplace into the neighbouring market for e-commerce logistic in which Amazon operates¹⁸¹¹. This leveraging can also reinforce Amazon's dominant position in the e-commerce marketplace, as it may lead sellers who want to be effective on Amazon Marketplace to forego the duplication of costs implicated by alternative logistic arrangements and ultimately abandon other marketplaces altogether¹⁸¹².

News report in June 2019 indicated that the FTC was investigating three practices of Amazon that related to its status as a dual distributor, although the FTC has declined to comment on the case¹⁸¹³. However, FTC Chairman Joe Simons publicly confirmed the ongoing investigation¹⁸¹⁴.

The first practice that the FTC allegedly was asking Amazon's rivals about concerned how Amazon priced its fulfillment services. These services consist of storing goods in Amazon warehouses and having Amazon pack and ship orders, and interact with customers about the orders. Many orders occur on Amazon, but Amazon offers the same services for sale off the Amazon platform, whether the manufacturers' own website or another online marketplace. Amazon charges about 75 percent more for fulfillment of purchases that customers make outside of Amazon: \$8.35 instead of \$4.76 to select, pack, and ship an item that weighs between one and two pounds.¹⁸¹⁵

The FTC will have to guard against imposing disadvantages on Amazon relating to practices that offline retailers utilize. Amazon competes in several markets against Walmart, for instance.

The third area of questioning purportedly targets bundling services centered on Amazon Prime. \$119 will buy customers unlimited one-day shipping, access to TV shows, movies, and songs, free online photo storage, and other perks.¹⁸¹⁶ The FTC may be checking whether the bundle permits Amazon to exclude entities that compete in the linked market. Amazon may take its profits elsewhere on the platform. Yet for some of these services, Amazon grows the size of downstream markets and the linked market. It pays for more TV shows, movies, and songs, and it will have difficulty excluding Apple and Netflix. Amazon lacks market power in nearly all of these markets including shipping services, where it competes against the U.S. postal service, UPS, FedEx, and DHL. Amazon designed the bundle to exploit network effects and to exclude at the level of the platform, against rivals whether online or offline.

Another potential area of investigation concerns Alexa and its early lead in the smart home space. The FTC may be focusing on Amazon's role as a dual distributor and the terms of competition that it offers to manufacturers that incorporate Alexa into their devices, or developers that create apps for Alexa.¹⁸¹⁷ Separately, Alexa may have a duty to rank customer requests, and to apply customer criteria, according to relevance.

Russia: The FAS has considered the issue of dual distribution while investigating cases of coordination of economic activity by LG Electronics and Apple.¹⁸¹⁸ In both cases, the

Russian subsidiary of the smartphone manufacturer was an exclusive distributor of smartphones in Russia. Both Apple and LG sold smartphones to authorised distributors and resellers and simultaneously operated as a retail seller of these smartphones. This means they were present at both levels of supply chain (wholesale and retail) and were involved in dual distribution. However, the FAS established that while Apple and LG sold smartphones only through brick-and-mortar stores, resellers organized retail sales through either brick-and-mortar or online stores or both. Based on this, the FAS concluded that they operated in different product markets and did not compete with each other. In the same time the FAS noted that resellers were not independent in setting resale prices for smartphones, as Apple and LG coordinated the level of prices for their smartphones and applied sanctions to those who deviated from the recommended resale prices.

It is noteworthy that in these cases the FAS focused on restriction of price competition between resellers at the retail level (horizontal element), rather than on the rent that the exclusive importer of smartphones potentially extracted through the vertical supply chain. Interestingly, the retail prices of, for example, Apple smartphones sold by Apple directly were considerably higher than those set by its resellers, even if coordinated by Apple.¹⁸¹⁹ This might indicate that Apple's strategy of dual distribution aimed at maximizing the joint profit through both channels rather than steering customers to its own distribution channel.

India: On the dual role of platforms, it is important to mention India's Foreign Direct Investment (FDI) Policy, where a distinction has been made between Multi Brand Retail Trading (MBRT) and Single Brand Retail Trading (SBRT). While imposing several restrictions on FDI-led MBRT platforms, the Policy has fewer restrictions on SBRT platforms (even if FDI-led) and domestic MBRT platforms. Foreign MBRT platforms are barred from adhering to 'inventory-model' (i.e. cannot hold stakes in suppliers on its platform) in B2C transactions, and have to strictly follow 'marketplace model' of e-commerce.

Restrictions regarding 'dual role' do not apply to domestic platforms but only on foreign owned platforms (Amazon and Flipkart are foreign owned in India). However, since 100% FDI is allowed in food product retailing, adoption of inventory-model (or dual role) in e-commerce of food & grocery (such as Swiggy, Zomato, Uber Eats, Food Panda; Grofers, Amazon Retail etc.) is still common practice¹⁸²⁰. But it should be noted that restaurants operating on platforms have been raising voice against platforms with their own cloud kitchens¹⁸²¹. As far as hotel sector is concerned, this seems to be in a gray area as

<https://solutions.fas.gov.ru/ca/upravlenie-po-borbe-s-kartelyami/ats-20961-17> and decision of the Federal Antimonopoly Service of the Russian Federation dated 02 March 2018 № 1-11-18/00-22-17 <https://solutions.fas.gov.ru/ca/upravlenie-po-borbe-s-kartelyami/ats-14552-18>.

1819 See, for example, Kommersant, 'FAS Has Brought the Case against Apple' (08 August 2016) <https://www.kommersant.ru/doc/3058629> accessed 14 August 2019.

1820 <https://economictimes.indiatimes.com/industry/services/retail/amazon-retail-ups-pantry-play-after-clarity-on-fdi/articleshow/67877279.cms?from=mdr>

far as any restrictions on dual role is concerned. Things may get clearer in near future, as complaints are currently being raised by hotel associations against platform owners, including before the Competition Commission of India. The CCI recently decided in favour of a hotel booking platform (OYO) in a case alleging abuse of dominance – *RKG Hospitalities Pvt. Ltd. Vs. Oravel Stays Pvt. Ltd*¹⁸²²

It should further be noted that the Consolidated FDI Policy, 2017¹⁸²³ contains specific rules applicable to e-commerce marketplace: first, they may provide support services (like warehousing, logistics, order fulfilment, payment collection etc.) to sellers¹⁸²⁴ only if on a fair and non-discriminatory basis.¹⁸²⁵ Secondly, they must not exercise ownership or control over any vendor on its platform,¹⁸²⁶ including through group companies and by way of equity participation or control of the inventory,¹⁸²⁷ and shall in any event maintain a level playing field and refrain from influencing the sale price of goods or services, directly or indirectly.¹⁸²⁸ Third, they must not require sellers to offer any product exclusively on that marketplace.¹⁸²⁹

Finally, the full picture of the regulatory framework is completed by the draft National e-Commerce Policy, issued on 23rd February 2019 by the Government of India (Department for Promotion of Industry and Internal Trade, Ministry of Commerce and Industry)¹⁸³⁰ inviting stakeholders' comments. The draft Policy, bearing tag line "India's Data for India's Development", requires e-commerce entities to make full disclosure to consumers regarding the 'purpose' and 'use' of data collected¹⁸³¹.

6.3.6. 'Enveloping' and bundling strategies

Enveloping and bundling strategies are examined in detail in the Chapter relating to abuse of dominance as most cases involved the use of bundling by dominant digital platforms. We have not identified any bundling or enveloping case by a non-dominant firm in the context of agreements with distributors.

6.4. Conclusions

The above analysis has illustrated the importance of policing vertical restraints in e-commerce, and more generally in a platform-mediated marketplace. Although platforms offer but one possible channel to bring products to the market, they provide a

1831 Para 3.8, p21, draft National e-Commerce Policy

readily available distribution network and unprecedented scale at great convenience, which is typically impossible to match for any seller. In that connection, there is increasing tension between the attractiveness of this model and the potential cannibalizing effects that relying on platform sales might have on one's own distribution channel. MFN clauses play an important role in that regard, as they enable platforms to ensure price parity with other channels. Hence, the stance that competition law takes in regard to these practices can have significant effects on the structure of the retail market. An important related question is the extent to which outrights bans to use platforms or price comparison tools for certain products are compatible with competition law. However, this has not been an issue in any of the BRICS jurisdictions, where platforms have been perceived as offering a unique opportunity to reach the target audience and enforce selective distribution systems, facilitated by the increased ability to monitor and detect deviations from selective distribution systems (while also, possibly, to enforce RPMs). Digital technologies also facilitate the enforcement of price discrimination, not only in a geographical sense (for instance through geoblocking, geofiltering and other technological protection measures) but also in a much more granular sense, by the increasing use of targeting and personalized pricing, which is examined in a separate Chapter of this Report. With regard to content distribution, it was noted that there are reasons to doubt that BRICS jurisdictions will condone the extension outside the protected territory of contractual restrictions imposed by copyright owners onto platforms, which are applying in the EU and constitute a reflection of the stricter EU copyright regime. This suggests that BRICS economies are likely to maintain a significantly different landscape for content distribution and copyright enforcement, despite the global or macro-regional nature of prevalent platform businesses.

With the increasing platformization of retail, perhaps the most contentious topic is the compatibility with competition law of the dual role played by e-commerce operators, which serve both as "referees" in the market place and as retailers operating in that market. This is an issue that is currently being investigated or has been subject to investigation in several EU jurisdictions, the United States, Russia and India. India has gone as far as issuing a comprehensive regulation on e-commerce and foreign direct investment policy forcing foreign-owned platform to be merely a marketplace, rather than provide products through their own inventory, to refrain from imposing exclusivity and to maintain a level playing field. Whether this policy of *ex ante* regulation is preferable to antitrust enforcement and is likely to be followed by other BRICS jurisdictions remains to be seen. However, what is clear is that in this new technological environment competition authorities and courts are called to play increasing attention to the dynamics of competition within and across platforms ecosystems.

Authorities should be cautious with the application of the so-called agency immunity, as that applies only under restrictive conditions. Most notably, the immunity cannot apply where one of the parties has significant market or even bargaining power, either in the platform market or in the market for the product or service in question. This is particularly important as platforms may be able to impose on members of their ecosystem

vertical distribution restraints (such as APPAs) to increase their power and then exploit their superior position without having to worry too much about market contestability. A similar dynamic applies to consumers, who are typically single-homing and locked in, or at least reluctant to abandon the convenience of wide variety of products at the cost of a click, and lack the ability to appreciate price discrimination and other forms of exploitation.

Finally, the immunity cannot be invoked where the arrangement between the putative agent and principal involve horizontal collusion. This is an area that has seen significant enforcement, particularly in Russia and India, where authorities have condemned platform-enabled hub and spoke agreements. Once again, queries can be raised as to whether it would be prudent to extend this approach across the entire BRICS.

TableAnnex 6.21: BRICS NCAs Feedback on Vertical Online Restrains

Vertical online restraints	BR	RN*	IN†	CN‡	ZA
In your jurisdiction, what is the approach followed with regard to vertical online restraints?	A rule of reason approach	Up to the moment the FAS Russia has no enforcement experience on vertical online restraints.	No information available	Per se illegality approach A rule of reason approach	A rule of reason approach A structured quasi per se illegality approach Per se illegality approach
In particular, what is the approach followed with regard to: Geo-blocking/ geo-filtering practices	Resolution CADE 20/99 has a specific provision on territory restrictions and customer base, by which the manufacturer determines geographic boundaries to the operation of the distributors or dealers. Accordingly, practices of this nature may restrict competition and competitors' entry in several regions, facilitating collusive practices and unilateral increases of manufacturers' market power. Nevertheless, considering that the practice shall be analysed under the rule of reason, Resolution CADE 20/99 also provides that the possible benefits in terms of transactional cost savings should be taken into consideration when reviewing these cases.	Up to the moment the FAS Russia has no enforcement experience on vertical online restraints.	No information available	A rule of reason approach	A rule of reason approach
Selective distribution in an online world: online commerce bans, restrictions on the use of marketplaces and/or price comparison tools	The Brazilian Competition Law does not provide for any specific guidance in respect to selective distribution. Nevertheless, an assessment by CADE will likely be made under the rule of reason on a case-by-case basis, balancing the anticompetitive effects and the economic efficiencies of the practice.	Up to the moment the FAS Russia has no enforcement experience on vertical online restraints.	No information available	A rule of reason approach	A rule of reason approach

	In addition, the assessment would likely relate to some of the provisions established by Resolution CADE 20/99 for restrictions on territory and customer base or refusal to deal. Their potential anticompetitive effects, therefore, could be related to blockage to, and increase in, barriers to entry into the distribution or supply channels.				
Most Favoured Customer/Nation (MFC/MFN) clauses, also called Parity clauses	A recent case of unilateral conduct in the digital market involved three major online travel agencies (OTAs) operating in Brazil (Booking, Expedia, and Decolar), which were investigated due to the adoption of MFN clauses. According to the General Superintendence, such clauses may restrict competition between the OTAs in question and other OTAs and hinder new platforms from entering the market. The case was closed with cease-and-desist agreements involving the three companies, in which the companies agreed to cease the adoption of wide MFN clauses, but the use of narrow clauses was allowed, so that the companies could request parity treatment with regard to websites of the accommodation providers. This agreement was based on the understanding that prohibiting MFN clauses under all circumstances might give hotels incentives to free ride and offer deals at lower prices than the ones announced on the OTAs platforms.	Up to the moment the FAS Russia has no enforcement experience on vertical online restraints.	No information available	A rule of reason approach	A rule of reason approach
Online RPM and RPM facilitating conduct: Minimum Advertised Price Agreements (MAPs) and dual pricing restriction	The law lists 'to impose on the trade of goods or services to distributors, retailers and representatives, any resale prices, discounts, payment terms, minimum or maximum quantities, profit margin or any other market conditions related to their business with third parties' as one of the possible anticompetitive conducts. Resolution 20/99, in turn, also includes a specific definition of resale price maintenance (RPM), meaning the manufacturer establishing,	Up to the moment the FAS Russia has no enforcement experience on vertical online restraints.	No information available	Per se illegality approach	A rule of reason approach

	<p>in an agreement, the price (minimum, maximum or fixed) to be adopted by distributors or dealers. Said Resolution consolidates the understanding that fixing minimum prices often results in anticompetitive effects, usually related to easier collusive price practices and increases the manufacturer market power, deterring the entry of more competitive distribution and reducing intra-brand competition. CADE precedents show that the practices considered legal are usually those related to suggestion of resale prices. On the other hand, minimum resale prices, especially when associated with monitoring and punishment measures, tend to raise relevant concerns from CADE's perspective. The legality of MAPs was discussed in a recent consultation presented to CADE by Continental. Continental intended to implement an MAP to its retail distributors in the aftermarket tyres segment, aiming to preserve its business model. After recognizing the ambiguous effects generated by the MAP to consumer welfare, CADE concluded that the policy to be implemented by Continental was legal, considering: the absence of market power; the fact that the MAP was unilaterally designed by Continental; and the absence of any type of discrimination between Continental's distributors.</p>				
Leveraging/ Tying/bundling practices	<p>The law lists the practices of leveraging, tying and bundling as possible anti-competitive conducts, which shall be analyzed under the rule of reason.</p>	<p>Up to the moment the FAS Russia has no enforcement experience on vertical online restraints.</p>	<p>No information available</p>	<p>A rule of reason approach</p>	<p>A rule of reason approach</p>
<p>In particular, in your view are the existing rules under the relevant national competition laws sufficient to address vertical restraints in the digital economy?</p>	<p>YES</p>	<p>Proposed amendments do not address the issue of vertical restraints</p>	<p>No information available</p>	<p>The basic framework and principles of the existing Anti-Monopoly Law are sufficient to deal with the competition caused by the digital economy. The Anti-Monopoly Law protects fair competition in the market, which means that all operators are equal</p>	<p>Jurisdictional reach is a challenge for authorities in these cases as competition authorities may sometimes struggle to hold to account global entities with limited presence in South Africa.</p>

				<p>before the law. The Internet sector is also regulated under the Anti-Monopoly Law. Any operator that violates the Anti-Monopoly Law must accept the investigation of the national competition authorities and assume corresponding legal liabilities. The State Administration for Market Regulation, responsible for the unified anti-monopoly law enforcement in China, attaches great importance to the competition in the new economic field. The State Administration supervises the development of emerging fields such as the Internet according to the principle of inclusiveness, protects fair competition in the market, and provides an inclusive development atmosphere for new Internet formats and new operation models.</p> <p>It is necessary to fully utilise market mechanism, enhancing the role of innovation in driving the Internet industry; it is also necessary to improve the Internet industry's regulatory system, working synergistically with relevant departments, strengthening market surveillance in accordance with the law, effectively regulating the competition of platforms, investigating the alleged anti-competitive conduct, preventing the formation of industry monopolies and market barriers, protecting the legitimate rights and interests of consumers and the public interests, and guiding the healthy and orderly development of the Internet industry.</p>	<p>This is especially where the evidence is located elsewhere and the authority faces numerous legal hurdles to securing that evidence, typically without success. Limited resources and the complexity of digital market cases are a further impediment to effective market conduct enforcement in a developing country context.</p>

Source: Information provided by NCAs of BRICS countries

* Up to the moment, RU and ZA have no enforcement activity in vertical online restraints.

† India: no feedback received.

‡ CN: At present, the same provisions apply to both online and offline vertical monopoly agreements. Article 13(2) of the Anti-Monopoly Law states that the term “monopoly agreements” refers to the agreements, decisions or other concerted behaviours that may eliminate or restrict competition. Article 14 stipulates that business operators are prohibited from reaching any of the following monopoly agreements with their trading parties: (i) fixing the price of commodities for resale to a third party; (ii) restricting the minimum price of commodities for resale to a third party; or (iii) other monopoly agreements as determined by the Anti-monopoly Law Enforcement Agency under the State Council.

Chapter 7. Exclusionary and unfair unilateral practices in reference to Platforms

**Bjorn Lundqvist, Ioannis Lianos, Wang Xianlin, Matt Strader with Igor Nikolic,
and the BRICS teams**

7.1. Introduction

There is an intense academic discussion regarding whether consumers and business users are exposed to conduct that may amount to competition law abuses when using services on the Internet. The discussion is connected to the Internet phenomenon of ‘platforms’ or intermediaries, i.e. Internet sites where users and potential purchasers of services and products are matched and interact with advertisers, business users, service provider or suppliers. Indeed, the rise in importance of platforms – as an intermediate – in all branches of industry is obvious to everyone.¹⁸³² Yet, the consequences of this paradigm shift in the value chain is not clear.

Internet platforms may due to certain special and somewhat unique characters, like network effects, tipping and path dependency, become central ‘hubs’ in the digital value chain and bottlenecks in the vertical interface between purchasers and suppliers.¹⁸³³ The economists seem to tell us that only a limited number of platforms may exist on the Internet, hubs in separate large ecosystems consisting of a main service, the platform, and several connected neighbouring services.¹⁸³⁴ Well-known ecosystems mainly focused on marketing to consumers are the Google and the Amazon ecosystems, while there are also Industrial Internet platforms and ecosystems being developed.¹⁸³⁵

In each ecosystem, a platform constitutes the central arrangement in the digital value chain between business users and consumers. The multitude of direct customer – supplier transactions are to an increasing degree replaced on the Internet by an intermediate, the platform, matching the customer with the supplier. Platforms are able to do so because they provide efficient and easy purchases. Choice is reduced on platforms since consumers/users to a higher degree delegate the purchasing decisions to inter-

1832 There are several forms of platforms, especially, when taking into consideration Internet of Things and Industrial Internet. For an overview see *supra* chapters 2 and 3. See also Geoffrey G. Parker, Marshall W. van Alstyne & Sangeet Paul Choudary, “Platform Revolution: how networked markets are transforming the economy and how they make them work for you”, W.W. Norton, New York, 2017.

1833 See discussion *supra* Chapters 2 and 3.

1834 *Ibid.* Jacques Crémer, Yves-Alexandre de Montjoye, Heike Schweitzer, Competition policy for the digital era, Final report, 2019, 5.

1835 See generally Ying Zhang, et al “Long/short-term utility aware optimal selection of manufacturing service composition towards Industrial Internet platform,” in IEEE Transactions on Industrial Informatics.

mediaries, abdicating the need to stay informed to be able to take the right commercial and business decisions by handing over the relevant personal and non-personal data to intermediaries to make or simplify the decision for them. The intermediaries select the level of price and quality that customers view, which can change based on personal data.¹⁸³⁶ Finally, there is a lock-in effect, where both businesses, by making use of platforms providing customers, and individuals, by providing their data and delegating commercial decisions to the platforms, will become dependent on the intermediaries to make decisions for them.

Generally, the platform business activities are addressed today under competition law mainly on three different levels and even though there are overlaps, perceiving the industry in levels works well.

First level, the competition between platforms or ecosystems, ie inter platform competition, and while the competition at this level seems fierce, there are incidents which might amount to competition law violations. For example, platform providers regularly exclude or refuse services of competing platform providers on their respective platforms.¹⁸³⁷

Secondly, there is a relevant discussion regarding the restraints the system leaders of the platforms or ecosystems burden the business users connected to the ecosystems. Indeed, intra platform or intra ecosystem competition is a relevant notion. Business users wanting to be recognised and present in the ecosystems and on the central platforms needs to agree on terms and conditions that might cause exclusion of competition, or which might be considered unfair.

Thirdly, in reference to data, several Internet sites, devices and machines are already today equipped with sensors to collect data and devices may run software to control and make interoperable the functioning of machines, but also to enable the interoperable smart kitchens, vehicles, and even cities. The system leaders of these smart interoperable systems may act as gatekeepers, controlling and locking-in customers, while excluding or limiting interoperability with other systems, specific device or machine producing firms and customers, based on the access, use and re-use of data. The technic for excluding firms could be contractual, technical (based on private or privileged private application programming Interfaces (APIs)), or based on superior data access. The restraints may at a first glance be seen as vertical, but, may, at a closer look be horizontal since the system leader is either vertically integrated or the restrictions aim to fend off potential or system related competition. Indeed, access to up-to-date data (nowcasting¹⁸³⁸) may often blurr the boundaries of relevant markets and also the divide between

1836 Paul Belleflamme & Martin Peitz, *Industrial Organization Markets & Strategies* 663-64 (2010); Mark R. Patterson, *Anti-trust Law in the New Economy* 75 (2017).

1837 See for example Google and Amazon feud that ended with a truce regarding streaming technology and features. Google will let Amazon have a real YouTube app on its Fire TV platform, and Amazon will expand Prime Video support to Chromecast and all Android TV devices. Ryan Whitwam, *Amazon, Google Finally End YouTube Streaming Feud*, on April 18, 2019, <https://www.extremetech.com/internet/289858-amazon-google-finally-end-youtube-streaming-feud>. See also Spotify complaint to the European Commission regarding "the Apple tax".

1838 Nowcasting is the capacity of a company to use the velocity at which a dataset grows to discern trends before others

horizontal and vertical, diminishing the difference between inter and intra ecosystem competition.

For the above-described conduct to amount to an abuse of dominance, the system leader (or platform) needs to be considered dominant. This issue has been discussed *supra*, yet will be revisited in this chapter.

For the first scenario, the platform v. platform competition, the issue is to identify relevant market power. The business models for platforms are different, some sites focus on retail, connecting sellers and purchasers for purchasing products and services, some platforms are social sites, e.g. dating sites, while others focus on general and vertical search.¹⁸³⁹ Several of the platforms and ecosystems compete intensely, while still provide a conglomerate portfolio of services. They generally, thus, compete for users and consumers limited attention span¹⁸⁴⁰, while still often being active on specific platforms service markets, as well as on downstream or aftermarkets within the ecosystem provided around their successful platforms.¹⁸⁴¹

The second scenario described above concerns ecosystem around a platforms, *inter alia* the neighbouring, downstream or aftermarkets. The thesis being that a system leader that have been able to utilize direct and indirect network effects, and restrict data flows can tip the specific platform market for consumer attention, so that consumers for the platform service turn to the system leader's platform. The system leader would then be able to control the platform with thereto connected ecosystem – the sole central arrangement in the network for scarce resources – and gain market power inside that network, to a point where the system leader becomes a 'winner takes all or most'. The platform will be the only relevant hub and GateKeeper in the ecosystem and the other sites, services and business users enclosed in the ecosystem are dependent on the platform and have a vertical relationship to the platform.

Successful platforms that have been able to tip the market for the platform service may obtain power not only in reference to the platform service market, but more importantly also in reference to the connected business users utilizing the service. Indeed, the system leader controlling the platform has gained power in the whole connected ecosystem to the point where it commands the interaction of the ecosystem. Under EU Competition Law, such ability to control whole ecosystems may trigger the special responsibility doctrine, where the dominant firm need to ensure a competitive levelled playing field

do. Nowcasting enables a firm not only to track trends in users' conduct in real time, but also to monitor trends in (potential) competitors' conduct, and to respond more quickly, which helps it push or nudge the market. Daniel L. Rubinfeld and Michal Gal, 'Access Barriers to Big Data' (2017). 59 Arizona Law Review 339. Available at SSRN: <https://ssrn.com/abstract=2830586> or <http://dx.doi.org/10.2139/ssrn.2830586>, accessed 12 December 2017.

1839 There exist several different platforms. See Jacques Crémer, Yves-Alexandre de Montjoye, Heike Schweitzer, Competition policy for the digital era, Final report, 2019, 54 et seq.

1840 Wu, Tim, Blind Spot: The Attention Economy and the Law (March 26, 2017). Antitrust Law Journal, Forthcoming. Available at SSRN: <https://ssrn.com/abstract=2941094> or <http://dx.doi.org/10.2139/ssrn.2941094>

1841 The concept of aftermarket should be used with caution. Aftermarkets give rise to several kinds of questions under competition law. For example, does a relevant market for competitive analysis consist of separate markets for primary and secondary products, or is it a market for "systems" consisting of both primary and secondary products?

on the downstream or aftermarkets.¹⁸⁴² That the platform specific standards and rules that it selects for its platform do not impede free, undistorted and vigorous competition on connected markets without objective justification, because in essence dominant platforms have won the competition, become monopolists and are regulators of their respective ecosystems or, hence, their respective networks for scarce resources.¹⁸⁴³

Moreover, in reference to the third scenario, regarding data, it represents a new dimension for conducting competition. The amount and uniqueness of the data obtained by firms may represent power on separate data markets, while the data may still be a tool for competing and for power on levels one and two. This will be further developed below.

This chapter will deal with possible conduct that might arise to monopolisation or abuse of dominance in these scenarios, discussing, without the aim or intent of covering this area fully, the broad question what exclusionary and unfair unilateral practices¹⁸⁴⁴ are relevant in reference to data, and, hence, should be prohibited under competition law?

May preventing interoperability, access to ecosystems or IT-systems and preventing portability of data, be considered abuse or monopolisation? Should discrimination, by not creating a levelled playing field, or by not displaying similar business users, on equal term, in search results or on product/services comparison sites be an abuse? Can restricting access to data be an abuse? Several of these issues are raised in this chapter and even though there are often no clear answers, a framework or methodology will develop for how these questions may be approached.

The chapter is divided in three main parts. Firstly, shortly discussing the structure and the perception of dominance and power in the digital economy. Secondly, a more in-depth discussion regarding conducts that amount to abuses is presented and the various economic arguments succinctly presented. Thirdly, the chapter concludes with a comparative analysis of the case law and decisional practice of the BRICS competition authorities, also comparing with the way the US and the EU have dealt with these practices, also providing some broader directions to competition law enforcers in these jurisdictions.

The chapter focuses on conduct that may be considered antitrust harm, reference to economic conduct, using an evidence-based approach. While the suggested framework presented in this chapter builds on the notion that successful platforms have obtained power in their ecosystems to a point where the system leaders command, 'regulate', their respective networks, and that the threshold for abuse therefore needs to correlate to such heightened responsibilities. Implicit in this analysis is that we are also taking the view that business users (producers) sometimes need to be protected because of the effects that monopolistic platforms may have on innovation and productivity within the ecosystems connected to the platforms. Notwithstanding this, the long-term effects of

1842 The system leader can be regarded as the regulator or standard-setter for the ecosystem. Jacques Crémer, Yves-Alexandre de Montjoye, Heike Schweitzer, Competition policy for the digital era, Final report, 2019.

1843 See generally *ibid.*

1844 Non-price exploitative practices are examined in Chapter 8.

data collection and data analysis are not clear and the effects of individual delegating commercial decisions to intermediaries should neither be underestimated nor undervalued. A system that takes away the power to decide from individuals threatens other societal values then can be summoned under the limited notion of antitrust harm. In the end, private autonomy, the right to self-determination, is at stake, while from a consumer welfare perspective, the independent consumer, the king of the market, by delegating his right to decide, are getting less important for the competitive process. The question is whether and how this should be addressed under competition law. Traditionally, competition law protects to a certain extent variety, choice and innovation, while it is not directly protecting the personal development or independence of individuals. It is rather protecting competition to the benefit of consumers. Indeed, the development of platforms – central administrative units – making the relevant decision for the competitive process – by delegation from users and consumers – is a fundamental change of liberal economics as we know it, and beyond the aim of this chapter¹⁸⁴⁵. However, this issue is addressed in the conclusion of this report.

7.2. Dominance Based on Control and Access to Ecosystems

7.2.1. Controlling ecosystem and networks equals power under competition Law?

Under the classical methodology using relevant market and the SSNIP-test, it is difficult to identify market power in the digital economy. Among platforms, Google and Facebook have been accused of holding market power due the popularity of their respective sites/ecosystems and their advantage in data or knowledge of their users, but is that important in a future IoT setting, where the amount and quality of data might be what create market power? Or, when they are active on two or more markets (double sided markets) simultaneously? Are there double or multisided markets?¹⁸⁴⁶ Does such definition of the relevant market promote the competition law analysis?¹⁸⁴⁷ What about market power based only on the amount, quality and importance of data? Could such a set-up imply market power?¹⁸⁴⁸ In reference to establishing dominance, how do we quantify

¹⁸⁴⁵ See the analysis in Chapter 4.

¹⁸⁴⁶ David S. Evans and Michael D. Noel, 'The Analysis of Mergers that Involve Multisided Platform Businesses' (2008), 4(3) *Journal of Competition Law & Economics*, 663-695; and Lapo Filistrucchi, Damien Geradin, [Eric van Damme](#) and [Pauline Affeldt](#), 'Market Definition in Two-Sided Markets: Theory and Practice' (2014), 10(2) *Journal of Competition, Law & Economics*, 293-339.

¹⁸⁴⁷ *Ibid.* Evans, Noel and Filistrucchi et al. agree that not all digital markets are multisided. For an interesting analysis concluding that e-platforms are not multisided markets, see John Newman (2014), 'Antitrust in Zero-price Markets: Foundations', 3 et seq. https://scholarship.law.upenn.edu/cgi/viewcontent.cgi?article=9504&context=penn_law_review, accessed 23 April 2018.

¹⁸⁴⁸ See Bundeskartellamt (2016). OECD, (2016) Big Data – Bringing Competition Policy to the Digital Era, 10 et seq. available at <http://www.oecd.org/daf/competition/big-data-bringing-competition-policy-to-the-digital-era.htm>.; the German and French Competition Authorities joint paper, (10 May 2016) *Competition Law and Data*, 7, 14 et seq., available at <http://www.autoritedelaconurrence.fr/doc/reportcompetitionlawanddatafinal.pdf>

data amounts? What is dominance in data, when the amount of data always grows? How does this relate to multi-homing, i.e., where many holders have similar data? Moreover, the data held can perhaps be duplicated without unreasonable effort. Thus, data may be difficult to monopolize, with few truly unique datasets.¹⁸⁴⁹

Indeed, establishing market power in reference to the digital economy raises many questions. The identification of dominance should also take into consideration the direct and indirect network effects, network externalities, advantage in data and the high risk of market tip to the favour of one firm. On the other hand, firms who have gained a 'winner takes most' position may still fall foul of a 'death spiral' where they lose both consumer and business users, breaking down the network because groups on either side of the platforms are triggering each other. However, such break down would be based on some kind of collective and transparent decision of at least substantial group users of one side of the network to leave the network, a collective action that seems to be rare, and difficult to organise. High quality data and better usability (predictive modelling tools), combined with a data-driven business model, may also quickly create and sustain dominance or even a monopoly positions since the system leader would be more informed of the needs of the users of the platform.¹⁸⁵⁰

Given the dichotomy described above, there seem to be indications that system leaders may have power to control their ecosystems. However, do they hold market power? Generally, given the methodology applied above – to divide the digital economy in three levels – would imply that at the first level, inter platform competition, platform market power should be identified in the relationship with other platforms. This might however pose a problem since the platforms that we know seem to be very different. Amazon, Google and Facebook are providing different services. Some scholars are suggesting that they are indeed not so different and are competing on a general attention market.¹⁸⁵¹ They are fighting for our eyes and interests. How much attention do users give certain platforms and ecosystems in reference to other forms of media and intermediates? Can market power be identified based on the time spent on a platform in relation to other platforms? Can users be locked-in to certain ecosystems and spend most their attention to them? Can we identify and suggest market power based on the level of attention a media is gaining? Or, do we still need to identify 'markets'. In the few cases Competition Authorities have scrutinized the digital economy, the courts seem to in-

stead find the platform service provided and even though being free of charge, identify this as a relevant market. See for example the *Google* cases, identifying general search as a relevant market.¹⁸⁵²

There is – on top of this – a general attention market where the platforms compete, irrespective the different services they provide, and where neither platform could be considered having a monopoly or a dominant position. However, even though acknowledging that there is a general attention market should not blur the conclusion that the service provided by the platforms respectively (often generally providing interoperability between business user and customers), may still be a service the respective platform monopolises.

At the second level, inter ecosystem competition, competition law doctrines such as an updated version of aftermarket could imply the identification of monopoly power and dominance within ecosystems, even though dominance cannot be identified at the first level.¹⁸⁵³ The core activities of the platforms and the theories of network effect, learning effects and the ease that certain services ‘tip’ need also to be taken into consideration both for inter and intra ecosystem competition. The doctrine of aftermarket is controversial and need to be developed. The theory of path dependency could be utilized to show that both purchasers and business users of ecosystems may over time become dependent and locked-in to certain networks, making the ecosystem or network the relevant arena for judging whether the system leaders holds power, or not. Indeed, the initial decision in favour of one ecosystem means that a large number of follow-on decisions is de facto already taken and no competition exists on this level. This concerns all products within the ecosystem, from apps to further devices, to Internet services. For these parts, products and services, the influence of users is reduced to a minimum. The initial buying situation comes at the cost of high path dependency for all further individual decisions. Institutional economics characterise such situations as situations of path dependence.¹⁸⁵⁴

With the current large platforms, as well as with Industrial Internet and with Internet of Things, it may be common that data will be collected and stored with the system leaders in the relevant Internet ecosystem. That the systems leader has entered into vertical agreements with business users in its ecosystems. The aim of these vertical agreements may vary, but generally is benign business contracts, while an ancillary restraint may be

1852 Case AT.39740 *Google Search* (Shopping), 27 June 2017.

See also Rupprecht Podszun, ‘Innovation, Variety & Fair Choice – New Rules for the Digital Economy: Expert Opinion for Finanzplatz München Initiative’ (FPMI 2017) available at SSRN: <https://ssrn.com/abstract=3243403> or <http://dx.doi.org/10.2139/ssrn.3243403> accessed 19 July 2019.

that the data or traffic produced by the business users in the system are shared or even exclusively belongs to the system leader. It seems moreover that the system leader use or give access to the data to firms that competet with the business users that generated the data in the first place. It thus use or gives access to user data to third parties arbitrary or in a discriminating fashion, even vis-à-vis the user.¹⁸⁵⁵

Notwithstanding the above, it is increasingly acknowledged that controlling data is key in the ability of firms to gain and hold market power.¹⁸⁵⁶ Access to and instant control of vast amounts of data¹⁸⁵⁷ creates competitive advantages for firms. The firm having the best and most timely access and control over the largest and best data-sets should be able to utilize this to learn about the market and customers, personalize products and gain a leading market position.¹⁸⁵⁸

In the current stage of development of the digital society, platforms are the main collectors of data, while also being bottlenecks and central administrative units in the networks they create. The system leaders are able to detach the direct customer – supplier interface, which is replaced by the intermediate, the platform. That imply that the platform not only acts as a retail service, it also collects and transfer commercial data regarding purchasers, products and suppliers.

1855 Björn Lundqvist, "Cloud service as the Ultimate Gate(keeper)", *Journal of Antitrust Enforcement* (2019), available at <https://academic.oup.com/antitrust/advance-article-abstract/doi/10.1093/jaenfo/jny013/5303705> accessed 13 July 2019.

1856 For example, the German Competition Act has been amended in 2017 stating that "access to relevant data is a potential source of market power". See also, e.g., Wolfgang Kerber, 'Digital Markets, Data, and Privacy: Competition Law, Consumer Law, and Data Protection' (2016) *Gewerblicher Rechtsschutz und Urheberrecht. Internationaler Teil* 639-647 <<http://dx.doi.org/10.2139/ssrn.2770479>> accessed 13 July 2018. There are several authors who purport that holding big data does not equate to market power. See e.g. Giuseppe Colangelo and Mariateresa Maggiolino, 'Big Data as Misleading Facilities' (2 June 2017) *Bocconi Legal Studies Research Paper No. 2978465* <<http://dx.doi.org/10.2139/ssrn.2978465>> accessed 13 July 2018. Generally, they argue that big data does not create a significant barrier to entry and they base their claims, inter alia, on the non-exclusive and non-rivalrous nature of data and a claimed ease of collecting it, while disregarding many potential entry barriers. Other scholars argue that the harm created by big data pertains mainly to privacy. Yet, these conclusions are based on the limited existing economic studies on big data, which often focus on one specific market (most commonly on search engines or personal data markets). See e.g. Daniel L Rubinfeld and Michal S Gal, 'Access Barriers to Big Data' (2017) 59 *Arizona Law Review* 339 <<http://dx.doi.org/10.2139/ssrn.2830586>> accessed 13 July 2018; Darren S Tucker and Hill B Wellford, 'Big Mistakes Regarding Big Data' (2014) 6 *Antitrust Source* 10; Maureen K Ohlhausen and Alexander P Okuliar, 'Competition, Consumer Protection, And the Right [Approach] To Privacy' (2015) 80 *Antitrust Law Journal* 121; James C Cooper, 'Privacy and Antitrust: Underpants Gnomes, the First Amendment, and Subjectivity', (2013) 20 *George Mason Law Review* 1129.

1857 There is a discussion regarding the definition of "data": does it encompass syntactic information, semantic information, or both; and where should one draw the line in reference to protecting "data"? See Josef Drexler, 'Designing Competitive Markets for Industrial Data – Between Propertisation and Access' (31 October 2016) 16-13 *Max Planck Institute for Innovation & Competition Research Paper 12 ff* <<http://dx.doi.org/10.2139/ssrn.2862975>> accessed 13 July 2019; Andreas Wiebe, 'Protection of industrial data – a new property right for the digital economy?' (2017) 12(1) *Journal of Intellectual Property Law & Practice* 67 <<https://doi.org/10.1093/jiplp/jpw175>> accessed 13 July 2019.

1858 Michael E. Prescott, *Big Data: Innovation & Competitive Advantage in an Information Media Analytics Company*, 4(1) *J. of Innovation Management* 92, 96-7 (2016); Maurice E. Stucke & Allen P. Grunes, *Big Data & Competition Policy* 89 (2016) at 183.

Secondly, the platforms provide, and will increasingly provide, an appreciated service since they to a high degree gain the trust to conduct or simplify the purchasing decisions for consumers. Purchasers abdicating the need to stay informed by handing over the relevant personal and non-personal data to intermediates to narrow the business decisions for them. The platforms will in the end hold the information and knowledge relevant to make the best informed decisions, and will be able to make connection not visible at first.

With the advance of the Internet of things (IoT), the amount of data that will be collected will increase immensely, also in industries that previously were not digital. Regular brick-and-mortar industry is likely to start including data-collecting sensors in the production of new products and within the products, and will, hence, become data collectors. The collected data will either be generated by the users of these products or devices, or by other devices when IoT components will start communicating with each other.

Further, future product markets will face a paradigm shift when data is included in the value chain.¹⁸⁵⁹ The vast amounts of collected data will influence the way the products are designed and developed, increase product quality, which in turn should generate best-matched products to buyers' expectations, as revealed by the data.¹⁸⁶⁰

This could alter old economy markets to focus even more intensively on demand features. Product cycles shorten. To a greater extent, businesses must have the resources to produce flexibly in real time. Survival may depend on this type of efficiency.¹⁸⁶¹

It is further feasible, that old oligopolistic markets will be transformed when one firm win the data-driven competition ('winner takes most') and become the system leader of specific systems, eg smart kitchens, vehicles. Indeed, the suppliers of individual devices to the systems, eg. the smart kitchen, may be excluded and degraded to suppliers or unequal partners of the system leader controlling the main platform.

However, the underlying forces of network effect and tipping may be controlled should the data in an ecosystem be free and accessible for all – like an open access of standard approach. Competition may increase since all members of the network ecosystem have access to the same data, and, in theory, become something akin to potential competitors. However, there are few if any relevant initiatives for creating such 'data commons', where data is freely accessible and open for all.

The services provided by Amazon, Google and other platforms, e.g., transaction site, cloud services, may constitute an example of the problem of few platforms controlling data and possibly gaining market power due to data-driven business model. It is not un-

1859 Ibid. 1861 Richard Cuthbertson, Peder Inge Furseth & Stephen J. Ezell, *Innovating in a Service-Driven Economy* 136-7 (2015), at 132-33.

common that Amazon, Google and other platforms have access to most, if not all, data in their respective ecosystems, while the business users in each ecosystem have limited access to data generated by them in the ecosystem. Moreover, the platform providers can have an advantage in controlling the best analytics tools. The platform providers may through their services and the collection of data on dominant platforms hold the knowledge of several industries, and with this advantage in data, they can eventually understand and learn users' markets, even though not being an active member of those markets. This may lead the system leaders to vertically integrate and with the use of data-driven business models take over regular brick-and-mortar markets, such as the markets for kitchens or cars.

A critical question is whether being a system leader and obtaining data from several participants in a market could amount to holding system market power, while not being active on those markets. Could control of data flows correspond to market power in the ecosystem and thereto connected markets.¹⁸⁶² For example, could a system leader having access to data from the majority of the firms active on a downstream market, be considered dominant in the upstream data market or on the product market?

The current probe by the EU Commission and the recently closed probe by the German Bundeskartellamt of Amazon address issues similar to what have been described above. According to Competition Commissioner Vestager, DG Comp opened a probe into Amazon's use of data on its third-party merchants. The idea was to assess the dual role of the e-commerce giant, given that it hosts but also competes against these other merchants. There are concerns that Amazon could be using sensitive information about its competitors' products to its own advantage.¹⁸⁶³

The German probe investigated supplemented the probe by the EU Commission, and the German Competition Authority analysed whether Amazon's terms and conditions were anticompetitively restricting business users. According to the terms and conditions, business users needed, for example, to assign right to use the information material which a seller has to provide with regarding to the products offered on pan-European despatch.¹⁸⁶⁴ Interestingly, the German Competition Authority indicated in reference to the issue of dominance that, "a necessary criterion for the relevance of this conduct under competition law is that Amazon holds a dominant position or that the sellers are dependent on Amazon. There are indications of both, in particular on a possible

1862 See the US Kodak case, *Eastman Kodak Co. v. Image Technical Servs., Inc.*, 504 U.S. 451 (1992), where the Court held that even though an equipment manufacturer lacked significant market power in the primary market for its equipment—copier-duplicators and other imaging equipment—nonetheless, it could have sufficient market power in the secondary aftermarket for repair parts to be liable under the antitrust laws for its exclusionary conduct in the aftermarket. For the EU see the Hugin case, *Hugin Kassaregister AB and Hugin Cash Registers Ltd v EU Commission*, Case 22/78, ECLI:EU:C:1979:138.

1863 See EU Commission Press Release Antitrust: Commission opens investigation into possible anti-competitive conduct of Amazon, 17 July 2019 available at http://europa.eu/rapid/press-release_IP-19-4291_en.htm accessed 17 July 2019. Cf. https://ec.europa.eu/commission/presscorner/detail/en/ip_19_4291 and

1864 See the German Competition Authorities press release: https://www.bundeskartellamt.de/SharedDocs/Meldung/EN/Pressemitteilungen/2018/29_11_2018_Verfahrenseinleitung_Amazon.html?nn=3591568.

market for marketplace services for online sales to consumers. This will be examined in closer detail by the Bundeskartellamt.” Thus, the German Competition Authority finds indication both for dominant position and – even though such dominance will not be identified – the business users using Amazon may still be so dependent of Amazon that in reference to their business relationship, Amazon may still hold bargaining power vis-à-vis the individual business users to the level where the German Competition law may be triggered. The German Competition Authority seemed here to stress that system leaders within their ecosystem may be considered powerful enough to trigger a German competition law violation, even though not being dominant on general (platform) service markets. In our methodology presented above, that would indicate that system leaders can be ‘dominant’ on level two (intra ecosystem) without being dominant inter ecosystem (level one). As will be discussed below, the German Competition Authority decided to close its investigation after Amazon agreed to change its terms and conditions.

Another set of important questions relate to whether the platform provider could be considered dominant on a non-market related innovation space for the future development of several products and services, i.e., being able to chill innovation incentives more generally.¹⁸⁶⁵

Interestingly, being the hub for data in its ecosystem, is a very advantageous position, also in reference of developing new innovation. Collecting data and making use of data analytics could be viewed as research and development, which is what large system leaders and platforms seem to be doing. These set-ups may be common. A system leader claims a right to access all data from business users. In reference to Internet of Things, for example, producers of different devices, e.g., different parts of a powertrain for a ship (parts that are all connected to IoT 24/7 and collect data), are forced to give the system leader advantage knowledge in reference to the data. The system leader gains data from the whole ecosystem making up the powering of the boat. That will enable the system leader to innovate in reference to the power of the boat, while parts producer will be left behind.

We can see the trend in reference to the known tech giants. It is not uncommon that Amazon, Google and other gatekeepers have access to most data in their respective ecosystems, even though users in each ecosystem have access mainly to parts of their own generated data.¹⁸⁶⁶ Moreover, Uber and some other e-ecosystems have a business idea where the system leader collects exclusively the data generated by their users business (the drivers), while the drivers do not have a right to port the data from their customers should they wish to exit the Uber system.¹⁸⁶⁷ Indeed, access and control of data could reflect market power.

1865 Se generally interesting discussion regarding research markets and competition in EUR. COMM’N, Case M.7932, Dow/DuPont, Decision C (2017), http://ec.europa.eu/competition/mergers/cases/decisions/m7932_13668_3.pdf (hereinafter, Dow/DuPont)

1866 Khan, “Amazon’s Antitrust Paradox”, 126 Yale L.J. (2016)

1867 Ibid. The EU Commission has recognised this problem in the proposed platform to business regulation (P2B) stipulates a rule that a platform provider must be transparent with the data it collects from its business users and if it intends to limit access to business users and give access to that data to its business users in a discriminating fashion. it needs to inform its business users, be transparent, about its business in-

Finally, it should be emphasised that algorithms and data analytics could be the bottleneck in the digital economy, rather than access to large data-sets¹⁸⁶⁸. It seems clear that for example some algorithms used and developed are better or rather outstanding compared to other software, and that data analytics connected to nowcasting could be the relevant competitive tool for the future. Indeed, the firm holding the best algorithms will be holding market power rather than the firm holding the best and largest dataset. However, before focusing on algorithms and IT infrastructure, the issue of data and dominance need to be further discussed.

7.2.2. What is data?¹⁸⁶⁹

Data could increase the network and learning effects, and be part of the dominance analysis, while data still also can be a separate third level where power can be identified. Firms controlling data flows from several sources connected to the same market, may have some degree of control and power on these markets and system leaders have power controlling data in the ecosystem.

Data, information or knowledge are often used interchangeably; however information becomes data when being digitalised or coded in some form suitable for better usage or machine processing. While the concept of data has historically been associated with scientific research, data are today collected by a huge range of organizations and institutions, including businesses (e.g., marketing, sales data, revenue, profits), governments (e.g., addresses, personal identification numbers, company registration data, unemployment data) and now sites and platforms on the Internet. The concept of data was explored in more detail at Chapter 4. Here we focus on some aspects that merit attention in the context of an abuse of a dominant position.

Raw data (“unprocessed data”) is a collection of digitised information before it has been “cleaned” and corrected. Data processing commonly occurs by stages, and the “processed data” from one stage may be considered the “raw data” of the next stage. Indeed, firms often want raw data, rather than processed data, to be utilized and processed for their business

A subgroup of data is personal data. A definition of personal data exists in jurisdictions where privacy and personal autonomy in reference to the digital society is protected. Generally, the definition of ‘personal data’ is broad. Any information relating to an identified or identifiable natural person (‘data subject’) should be considered personal data. The definition of personal data is wide since also information that is non-personal might indirectly in combination with other information identify a natural person and become

tent. European Commission, Fairness in platform-to-business relations, Ref. Ares(2017)5222469 – 25/10/2017. A District Judge in San Francisco recently found that by classifying drivers as independent contractors instead of employees, Uber significantly harmed competition under California state law. Daniel Wiessner, Uber’s classification of drivers may violate Calif. Antitrust law – judge, Reuters (21 June 2019).

1868 See the analysis in Chapter 4.

1869 For a more in-depth typology of data, from an access perspective, cf. chapter 3 *supra*.

personal data. Thus, non-personal, even raw or meta data, can in combination with other data become personal data under the definition.¹⁸⁷⁰

Up-to-date and relevant personal data may become the relevant competitive tool in several industries and markets. Access to relevant datasets may furthermore be indispensable to be able gain entry for firms wanting to access new markets and ecosystems. Access under general competition law – or sector specific competition law may be hindered if the holder of the personal data perceives it will violate data protection rules, should it sell, or be obliged to give access to firms. Indeed, data protection rules may work as barrier to entry, while competition law may oblige dominant data holders to transfer or give access to relevant datasets. Certain cases from national competition authorities in the EU have faced this dilemma. Where access to personal data was required, the UK and French competition authorities have solved this by ordering data access on an opt-out basis after taking advice from their respective data protection authorities.¹⁸⁷¹

Sometimes, a third option may be expedient and preferable, namely the implementation of technical tools that enable anonymous use of bundled individual data. It is therefore recommended that firms collecting data, even only meta data or aggregated data, even in an industrial internet setting, do take data protection rules in consideration. Indeed, it can be wise to calibrate the collection mechanism, in for example an industrial internet setting, so to be able to transfer non-personal data and to keep such data sets intact. It should be acknowledged that for competition to strive on the basis data and commercial use of data, the amount of data considered to be personal data cannot be excessive. Indeed, the definition of personal data should not be too wide, and when defining personal data, protection competition and rivalry need to be an necessary objective to take into consideration.

In the EU report on competition policy for the digital era, data is divided into four categories of uses: non-anonymous use of individual-level data, anonymous use of individual level data, aggregated data, and contextual data. Interestingly, the authors of the report seem to argue that anonymous use of individual level data is non-personal data and not a violation of the EU rules regarding data protection.¹⁸⁷² This is a practical approach that could be of value also for BRICS countries. The data are disconnected from any right on the behalf of the data subject.¹⁸⁷³

1870 Jacques Cr  mer, Yves-Alexandre de Montjoye, Heike Schweitzer, Competition policy for the digital era, Final report, 2019, 104.

1871 Ibid. See the French competition authority's interim measures decision no. 14-MC-02, of 9 September 2014, concerning Engie, at paras. 289 and 293-294; and the UK CMA's Final Report on its Energy Market Investigation, dated 24 June 2016, at para. 233 of the summary, and in more detail in paras. 11.64 to 11.66. In other cases, access to data for specified purposes and specified acts of processing may be mandated by a competition authority based on an interest balancing (Article 6 lit. f GDPR) or based on Article 6 lit. e GDPR which, inter alia, allows processing that is necessary for the performance of a task carried out in the public interest. See Jacques Cr  mer, Yves-Alexandre de Montjoye, Heike Schweitzer, Competition policy for the digital era, Final report, 2019, 104.

7.2.3. The blurring of data and physical: Data and the Internet of Things (IoT)

The internet of things (IoT) will develop during the next decade. It will connect devices digitally, and the link itself will create new functions. The real value in such markets will derive from collecting and evaluating data, however.¹⁸⁷⁴ Competition authorities will need to look for market power in systems, in which data will form a critical input, in addition to downstream product markets.

IoT systems present double-multisided markets. Data, advertising, identifying and anticipating preferences, purchasing, and nudging will function on one side of the platform. Sensors in products will enable this business model and create new product features on the other side of the platform.

Notwithstanding a symbiosis between the markets, they display distinct functions. Neither the producers of the devices nor the platform operator necessarily must conduct, or would be most skilled at conducting, data analytics. The platform will have an innate advantage in this task, or the sole right to it, because the platform collects the data centrally. Many different algorithms might best utilize that data for a given purpose. This generates gradations to the vertical relationship. The system bundles the function of a product, the joint functioning of products, data collection, and data analytics.

Closed systems, such as Apple, might require that consumers buy certain products. Yet Apple will operate at a disadvantage in this market, because open systems, offering sensors to all products, will collect more data and make more money. The freedom to refuse to deal with IoT systems may restrain their market power. The lure of a data set that best constitutes consumer preferences may coerce to an extent that approaches forcing.

The best indicator to this goldmine, if not an infallible one, is a record of what consumers have bought previously. E-commerce, search, and payments offer the most logical current vault for demand data. A few platforms, led by Amazon and Google, already have built such a data set.

The IoT will offer a different type of data. Instead of demonstrating what customers buy, it will show how customers use products. Data analytics will permit the system to offer to refill or substitute products before customers think to go shopping.¹⁸⁷⁵ Where dominant, the systems can exert tremendous control over purchases.

7.2.4. No one Owns Data

The data, the information (as such), irrespectively how private and how valuable, is not covered by property right in any jurisdiction.¹⁸⁷⁶ No one owns personal data, while still

1874 Maurice E. Stucke & Allen P. Grunes, *Big Data & Competition Policy* 89 (2016).

1875 Lynn Wu & Erik Brynjolfsson, *The Future of Prediction: How Google Searches Foreshadow Housing Prices and Sales* 89, in *Economic Analysis of the Digital Economy* (Goldfarb, A., Greenstein, S.M., Tucker, C.E., eds. 2015); Richard Cuthbertson, Peder Inge Furseth & Stephen J. Ezell, *Innovating in a Service-Driven Economy* 136-7 (2015).

1876 Josef Drexler, "Data Access and Control in the Era of Connected Devices – Study on Behalf of the European Consumer Organisation BEUC", 2018. There are authors that propose the recognition of ownership rights for consumers over

the 'data subject' may in certain jurisdictions hold some rights to the data.¹⁸⁷⁷

Notwithstanding this, if individual data points fulfils the requirement for an intellectual property right, e.g. copyright, it can be covered by copyright (3rd party copyright, or copyright held by firm that is also gate keeper to accessing the data in the server).

Whether the data may be covered by rules regarding trade secrets have up until recently been regulated very differently in the different countries.¹⁸⁷⁸ However, for example, in the EU, the regulatory landscape for trade secrets is dramatically changing with the introduction of harmonised rules based on Directive 2016/943/EU of 8 June 2016 on the protection of trade secrets. It is probable that non-personal and personal data may be protected under the rules in the directive. Individual data points might not constitute a trade secret, but the combination of data points or information (that as such is not publicly available), in a relevant data set, might well be considered a trade secret with commercial value.¹⁸⁷⁹

Moreover, in reference to data, the jurisdictions protecting databases (*sui generis* database rights), as for example Russia, may hence protect datasets or databases if the specific rules for such protection is fulfilled. Public and private entities that collect personal or non-personal data in databases might, thus, also fulfil the requirements for obtaining database *sui generis* protection, if the holder of the database has made a large investment in the creation of the database.¹⁸⁸⁰ According to the EU Commission, subject to exceptions, use by others (e.g., extraction of the content, reproduction or re-utilisation of the database) can be prevented by the database author or maker, but only to the extent that either its database in its entirety or substantial parts thereof are concerned, cf. article 7(1), or when others seek to use insubstantial parts of the database in a "repeated and systematic" manner, cf. article 7(5). The EU Commission concludes – in reference to the digital economy – that the protection offered does not apply to machine-generated

the data they produce: Chris Jay Hoofnagle and Jan Whittington, (2014), Free: Accounting for the Costs of the Internet's Most Popular Price, UCLA Law Review, Vol. 61, 606-670. available at http://papers.ssrn.com/sol3/papers.cfm?abstract_id=2235962.

1877 In the EU, there some rights connected to personal data in Articles 18-20 of the General Data Protection regulation, such as right to have data corrected, "right to be forgotten" and data portability. In reference to data portability, the right is however limited making it less attractive to change social website for consumers. Cf. Regulation (EU) 2016/679 of the European Parliament and of the Council of 27 April 2016 on the protection of natural persons with regard to the processing of personal data and on the free movement of such data, and repealing Directive 95/46/EC (General Data Protection Regulation) (Text with EEA relevance) OJ L 119, 4.5.2016, p. 1–88.

1878 Sweden is one of few states that have enacted a specific Act for the protection trade secrets, while, for example, trade secrets in the UK and in Denmark have been protected under case law and the marketing law (unfair competition law), respectively. In Sweden, collections of customer data, e.g. addresses, have been protected under the Trade Secret Act.

1879 See Josef Drexler, et al, (16 August 2016), Data ownership and access to data position statement of the Max Planck Institute for Innovation and Competition, Max Planck Institute for Innovation and Competition Research Paper No. 16-10, p. 6 et seq.

1880 British Horseracing Board, C-203/02 ECLI:EU:C:2004:128, para, 30 et seq. See also Drexler, "Designing Competitive Markets for Industrial Data – Between Propertisation and Access" (October 31, 2016). Max Planck Institute for Innovation & Competition Research Paper, No. 16-13, 21. Available at SSRN: <https://ssrn.com/abstract=2862975> or <http://dx.doi.org/10.2139/ssrn.2862975>.

data, while a certain amount of data needs to have been used for an infringement to be at hand.¹⁸⁸¹

In reference to data analytics, it is clear that data analytics contained in a software, or a algorithm contained in a software well can fulfil the rules for intellectual property rights protection. In the EU the software directive is applicable, while in the US copyright protection may be available.

From the general, brief, analysis above, even though possibly being a great source or wealth for the future, it is rather clear that data, be it big or open, personal or not, is not directly covered by any (intellectual) legal property system, while the data are kept confidential, apart and controlled under the platforms. Since data – generally – is not covered by a property right, legitimate access implies a right to commercial use the data.¹⁸⁸²

It is clear that in several jurisdictions the question of enacting a property right to data or data-sets, somewhat similar to the database directive in the EU, is discussed. In China and Russia such discussion have been initiated, and in India a proposition has been made in its draft National e-Commerce Policy (yet to be finalised) that data originating from conduct of the Indian citizens belong to India. A property right to data may reveal hidden values and assets.

7.2.5. Unique Data Sets and Competition Law

With the development of IoT, data have begun to grow at an explosive rate. Social changes have come to the fore and the concept of “big data” has emerged. Big data is not only an information asset with large data scale and diverse data types, but also a digital technology that specializes in data flow, management and value analysis. Its attributes are embodied in resource and technology. The strategic planning department of China defines big data from the perspective of top-level design: “Big data is a data set characterized by Volume, Variety, Velocity and Value (4V). At the present, large quantities of fragmented data of various formats are being collected, stored and correlation analysis of them are being conducted. Naturally, a new generation of information technology and service models are coming into being that can discover new knowledge, create new value and enhance new capabilities.”¹⁸⁸³ In order to avoid the text ambiguity caused by the mix of resource attributes and technical attributes of big data, this paper refers to the “data set” as a competitive factor with asset attributes in the big data market.

1882 See discussion *infra* regarding the interesting Chinese case *Maimai v. Sina* regarding whether non-legitimate accessing of data using an API may amount to a violation of unfair competition rules. Cf. <http://bjgy.chinacourt.gov.cn/article/detail/2017/04/id/2820264.shtml>

1883 China Government Network: Notice of the State Council on Printing and Distributing the Action Plan for Promoting Big Data Development (Guo Fa [2015] No. 50), http://www.gov.cn/zhengce/content/2015-09/05/content_10137.htm, last access date: February 15, 2018.

Data is ubiquitous, and almost all Internet behaviors produce corresponding data, but a single data type will not create any value. Only data sets that extract the value of information can reflect the market value of data as a production factor and a competitive resource. A data set is a relative concept. There is no specific measurement standard in quality or quantity. Its types include structured data that strictly follows the data formats and length specifications, as well as non-structured data such as files, images, geographic location trajectories, and personal choices and preferences.

Unique data sets have an important impact on market competition. First, data sets can be converted into transaction targets with exchange value after the process of definition, desensitization, information extraction, and value analysis. As a competitive product, this kind of information asset can bring direct product benefits and market advantages to entities that possess data. Second, dynamic, real-time data sets, coupled with algorithmic analysis techniques, help companies analyze market trends and identify consumer needs, thus gain unique competitive advantages in the relevant product markets. Third, if the type, scale and scope of a data set held by a company reach such a level that is impossible for the competitors to copy or surpass, then the market dominance of the company may have been formed and even will be strengthened. In this case, the company may gain a competitive advantage in upstream and downstream markets.¹⁸⁸⁴

It is precisely because of the special market advantages and competition effects brought by data sets that many companies increase their economic and resource input and strive to improve data collection capabilities and processing technologies. In the case of “Sina Weibo v. Maimai”, which is dubbed “the No. 1 case in the field of big data in China”, the Beijing Intellectual Property Court clearly pointed out that companies, pursuant to contract law and unfair competition law, may enjoy the exclusive right of the data which they have put in efforts and resources to collect. Therefore, others need to have legitimate access to the data and may not grab and use the data without permission and authorization.¹⁸⁸⁵

7.2.6. The Governance of Cloud and Market Power

In the context of digital economic development, data-driven companies have to deal with massive amounts of data generated by multiple channels at a rapid rate. The more data they mine, the greater pressure on their storage space, central processing units and algorithms. The increased basic inputs pose great challenges to the company’s capital base and technical capabilities. Virtualization technology has led to the birth of “cloud computing”. More and more businesses no longer use their own computer equipment but store and process data on a cloud computer platform provided by a third party.¹⁸⁸⁶

“Cloud” refers to integrated remote and information storage services. Information and

data generated, created and stored in the process of using cloud services are saved and kept in servers of cloud service providers who act as third-party data centers. The data kept in the cloud belong to the companies, but the cloud service provider has de facto control over the data, which has caused a concern in competition law. Does the governance of the cloud become a source of market power?

The key to the analysis of this problem lies in clarifying the role and positioning of the “cloud” – thinking about in what form the data exists, what role the cloud plays along the data value chain, and who owns or controls the cloud on the data.

(1) “Cloud” exists as a vehicle of data generation or capture. In this particular context, the cloud service provider is the main driver of data generation and thus the controller of the data. For example, the basic registration information is collected from the company customer for the specific needs of providing the service, or the product usage data and the daily operation behavior data are collected for the optimization and improvement of the product after obtaining the authorization of the company. At this point, the cloud service provider has exclusive control and dominance over the specific data sets it gathers. When these data sets constitute a critical input in the relevant market--difficult for others to replicate or substitute---, these can bring a competitive advantage to the cloud service provider. Under the circumstance of big data age, the control over the “cloud” helps operators obtain different types of data sets from different corporate customers to form differentiated data aggregates, thereby increasing the threshold for market entry or expansion of existing or potential competitors. Market barriers further while strengthening the market power of operators.

(2) “Cloud” exists as a data storage or warehousing center. The company simply delegates its data to the cloud data center based on the limited purpose of storing or expanding capacity, and the ownership and control of the data remains attributable to the company itself. Although cloud service providers have access to data, their use of data is strictly limited by the scope of corporate customer authorization. In this situation, the “cloud” is only the data storage space in the physical sense. The cloud service provider does not control the corporate data outside of the specific authorization, and in this sense its control does not bring new data assets to it.¹⁸⁸⁷

(3) “Cloud” exists as a data processing and analysis platform. Although it is not possible to directly use the data assets stored by enterprises to gain a competitive advantage, with the technology development and function expansion of the intelligent cloud platform, the providers can also enjoy positive market feedback brought by large-scale data streams. With the maturity of machine learning and artificial intelligence, many providers have begun to integrate databases and analytics engines into cloud platforms to provide enterprises with deeper value mining and business analytics services. In order to get a more intelligent solution, companies must authorize cloud service providers to access and control their own data in order to integrate external data and update solutions in real time. Continuous data feedback support, coupled with optimized algo-

rithms and machine learning, cloud services can better cater for enterprise needs, and even lead companies to trying new products.¹⁸⁸⁸

From different perspectives, the market power of “cloud” may vary in evaluation and measurement, but the meaning in competition law embodied in the “cloud” is far more than that. To some extent, the generation of “Cloud” can solve the problem of high amount cost of early input in data infrastructure. Cloud service providers convert these fixed costs into variable costs¹⁸⁸⁹ that small companies can afford, so that more corporations can get themselves involved into the wave of the digital economy.

As one of the forms of the Internet platform, “cloud” has typical characteristics such as multilateral market, dynamic competition and network effect. Due to the growing relevance and interconnectedness between platform users and data, the possibility for users to replace their provider is gradually reduced, and barriers to entry are increasing. For a fairly large cloud platform, as its users increase, the size of data will grow larger, the higher the users’ viscosity will move, and less likely its customers will leave them.¹⁸⁹⁰ As more and more customers rely on a small number of cloud service platforms, potential competitors will not be able to establish a strong enough data infrastructure, and it will be difficult for them to enter the market or compete with the existing operators. The cloud data market will slowly develop into an oligopoly.¹⁸⁹¹ Benefiting from the effect of economies of scale and economies of scope brought by cloud big data, the governance of “cloud” will bring incomprehensible competitive advantage and market power to market players.¹⁸⁹²

It is foreseeable that in the near future, BRICS competition authorities of law enforcement will focus on the competition law enforcement in the digital economy, especially the enforcement to the operators in the field of cloud services. Based on evaluating market power, the authorities will carefully examine different dimensions of operators’ participation in data-related market competition.

7.3. Different forms of Abuses in reference to Data

7.3.1. What may be considered as abuse in a digital economy?

There are several forms of abuses regarding prices and output, and the case law regarding such abuses are abundant. However, competition seems to operate differently in the digital economy. Indeed, several services provided on the Internet, are provided for free, so to increase the number of users, while this will attract business users on the other side of the platform to get access to the users. Along with data analytic capacity, platforms expend resources to attract users, whether on media content, facilitating user-generated content, or offering low prices, convenience, and selection. Interestingly, since the platforms offer many services for free to users, one side of the market is driven by demand. This can depend on the quality of results, products, or content, in addition to user restraints such as free time and the cost of connecting to the Internet. Demand and supply curves incorporate more sophisticated factors. However, the free side of the market exists only because businesses and customers are paying. In need of important channels for distribution or marketing, business users can have a difficult bargaining position.

In the digital economy, abuses seem to be centred around platforms. Firstly, the platforms may use anticompetitive conduct so to gain market power for the platform vis-à-vis other platforms (inter platform or ecosystem competition). Secondly, platforms may be used to favour or discriminate to the benefit of affiliated or directly owned firms in downstream or upstream markets. Indeed, platforms that have gained market power, being bottlenecks, invite the possibility of vertically integrated platforms to exclude competitors or to lock-in customers or business users. In addition, their control and use of data regarding their customers and users, and financial resources, platforms may have gained a leading role in their respective networks (the networks could be understood as different markets, a “social network” of actors that redistribute scarce re-sources within a certain order).¹⁸⁹³ They may exploit customers and business users by utilizing business strategies of, for example, personalised pricing, and exploitative tying.

To address the issue of platform dominance and abuse, we need to use competition law to regulate the underlying conduct that precipitates indirect (or direct) network effects and tipping, so to prevent monopolies from forming, while still not suppressing the incentive for firms to pursue platform-to-platform competition. Moreover, the issue is whether we should turn on the firms that gain monopoly position due to indirect network effects and tipping. We know that the firms that gain this position will most likely hold on to their monopoly position because it is very difficult to break a monopoly built on indirect network effects, tipping and path dependency.¹⁸⁹⁴

1893 Rupprecht Podszun, *Innovation, Variety & Fair Choice – New Rules for the Digital Economy: Expert Opinion for Finanzplatz München Initiative (FPMI)* (December 1, 2017). Available at SSRN: <https://ssrn.com/abstract=3243403> or <http://dx.doi.org/10.2139/ssrn.3243403>

1894 Jens Prüfer and C. Schottmüller, ‘Competing with Big Data’ (CentER Discussion Paper; Vol. 2017-007), Tilburg: CentER,

Competition authorities could respond by examining the source of competitive advantage. They would examine whether market power derives from characteristics on which rivals could compete. While superior quality usually enables an entity to acquire network effects when a market has not yet tipped,¹⁸⁹⁵ network effects can render a market un-contestable, regardless of the potential of subsequent competition. It may not have a chance to materialize. Enduring market power based on network effects resembles a government-sponsored monopoly, in that the winner does not sustain the position by competing on the merits. Taking this approach would not necessarily counsel in favour of regulation, but it would affect the strength of arguments related to access and investment incentives.

Consumers may prefer that a market tips. Most cannot be bothered by the hassle of multiple social networks. When competing for the network, to implement a data-driven business model or make use of network effects cannot, generally, in-itself be anticompetitive. These business strategies represent economies of scale or scope.¹⁸⁹⁶ Antitrust harms and potential effects need to be identified. Such conduct may, for example, be predatory conduct, tying, conglomeration etc. As case law stands today, it seems clear that anticompetitive harm and conduct needs to focus on exclusionary effects caused by the conduct of the dominant firm, outside the realm of competition on the merits.¹⁸⁹⁷

In addition to this, Competition Authorities need to acknowledge that platforms compete (inter platform competition), and that they compete for consumers and user attention, and the competition for users and consumers attention is fierce.

A way to address the issue that platforms may monopolize their core platform service markets, is to say that when a monopoly in a market driven by indirect effects has been established, the system leader controlling the platform is the 'regulator' of that network. There will be little if no competition for that network and the system leader therefore has a special responsibility to create a levelled playing field for downstream and connected markets.¹⁸⁹⁸ This could imply far-reaching responsibilities for the system leaders.

A competition problem in this regard on the Internet seems to be that firms (actual or potential competitors) are excluded or restricted from a platform or from a website that is necessary or indispensable for the firm's business. Exclusion may be clear-cut, the system leader refuses to grant access, or gives only access on anticompetitive exclusion-

Center for Economic Research.

1895 Some have argued better quality overwhelms the influence of network effects, with, perhaps, a lag of some years. Gerard J. Tellis, Eden Yin & Rakesh Niraj, Does Quality Win? Network Effects Versus Quality in High-Tech Markets, 46 J. of Marketing Research 135, 149, 153 (Apr. 2009), in *The Economics of E-Commerce* (Baye, M.R. & Morgan, J., eds. 2016).

1898 Jacques Crémer, Yves-Alexandre de Montjoye, Heike Schweitzer, *Competition policy for the digital era*, Final report, 2019, 69 et seq.

ary terms. It could also be subtler, that the firm is discriminated and are not visible on the platform website, gets less relevant data from the system leader than other firms in the ecosystem. Indeed, an Internet intermediate may be abusing their dominant position by leveraging that advantage to gain ecosystem dominance. The advantage in data may originate from a right to access and use customers data, and while such a clause may be considered anticompetitive in certain situations, an advantage may be caused without the use of specific potentially anticompetitive clauses, while it only reflects being the 'hub' for all relevant data in the ecosystem. In reference to data, new forms of abuses can be imagined, or we will need to revisit some of the established forms of abuse in order to update them for the era of digital competition.

7.3.2. Refusing or obstructing access to data/algorithms or interoperability

Whether entities operating on a platform can call upon refusal to deal law to enable access to data, algorithms or, generally, to avoid being excluded from ecosystems or infrastructure, will depend on different legal tests. To gain access to algorithms, which often benefit from IP protection, supplicants will need to satisfy the new product criterion in the EU, which requires material differentiation or improving upon the service offered by the dominant undertaking. In the U.S.A., supplicants must refute a presumption of validity concerning the business justification that the IP holder gives for not granting access. Businesses operating downstream on the platform will have to satisfy a more demanding legal burden to gain access to data analytics.

Looking at data, Amazon, for instance, invests immense sums in technology, its distribution system, cloud storage, and creating the context through which consumers express demand. Even if trade secret law or database right (copyright) does not protect the data, it still qualifies as an asset. And platform business models utilize data to monetize such investments. Amazon will say that the aggregate data it collects belongs to the platform. Absent the platform, the data of business users would not exist. EU privacy law has not recognized a right to port anything but the personal data of individual users. Absent competitive concerns, asset owners could point to the common attributes of ownership. A platform may select partners to sell services. It may charge to use the asset. In selecting partners, a platform reasonably might prefer those entities with a compatible business model, those that offer the greatest returns, or at least non-competitors. For competitors, it might demand that the business establish the indispensability of the asset for competition, before agreeing to grant access.

Interoperability implies two scenarios. Firstly, in the context of IT infrastructure, that there is horizontal Interoperability within IT and the world-wide-web. This does not imply net neutrality, only that there is interoperability horizontal between the various ecosystems. Often such interoperability is built of common technical standards. Secondly, in the context of big data, interoperability refers to the ability to achieve data and information sharing between different data subjects by applying common data structures and transmission standard settings. Interoperability creates the possibility of linking

platforms operating in different markets, through the exchange of data (horizontal data interoperability). It undoubtedly will promote data sharing and integration, improve the reuse of data sets,¹⁸⁹⁹ and may provide more applications and conveniences for data-driven enterprises and consumers. Platforms could gain from it. Interoperability also could drive further consolidation. Unless digital markets jointly accept horizontal data portability, platforms gain nothing from users leaving. A different balance may apply to vertical data interoperability, where business users and platforms exchange data within the ecosystem.

Platform data starts with the user, and the data is randomly captured without the user's consent, which may violate the data privacy protection regulations. The platform might actively restrict data interoperability for the benefit of the protection of user privacy.

Inhibiting data interoperability is not only a privacy or technical issue, but also an issue about competition and law. The openness or hindrance of data interoperability does not depend solely on whether it can be realized technically or whether it should be shared among operators. An important point is whether non-interoperability will damage the interests of users and the fair and free competition order.

A relevant, if not dispositive, question is whether platforms might choose to interoperate by participating in a market for data. Google has made data portable at the individual level, Amazon has not.¹⁹⁰⁰ A digital standard setter would have to create common interfaces. The major platforms all operate in separate markets, providing distinct, yet to a certain extent, overlapping, services. The fact that the platforms have not participated in creating a market for data reveals that data is a metric of competition. It also shows that they view the other platforms as offering a similar service, selling consumer preferences in tangible form, and creating markets.

When evaluating how a duty to interoperate might look, a court reasonably might distinguish between data that a single user or business might generate, and aggregate data compiled by all users of the platform. From a profitability perspective, platforms could part with individual data. Exporting larger data sets or categories of data risk diverting revenues away from the platform.

In justifying the possibility of imposing a duty to interoperate, a court might ask to what extent must platforms focus on consumer interests, particularly outside the platform. Platforms reasonably might argue that the scope of their responsibility to promote consumer interests should not extend beyond the platform, since they do compete with other platforms.

Closely connected to refusing access and interoperability of data, is refusing access to data analytics or algorithms, refusing access to technical standards needed to interoperate with platforms and ecosystems. Indeed, no access to IT-infrastructure. Refusing

1899 Josef Drexler et al., Data Ownership & Access to Data: Position Statement of the Max Planck Institute for Innovation & Competition of 16 Aug. 2016 on the Current European Debate, ¶ 40, Research Paper N. 16-10, <http://ssrn.com/abstract=2833165>.

1900 Online Platforms & the Digital Single Market, UK House of Lords Paper 129, ¶ 245 (20 Apr. 2016).

Interoperability or accessing data analytics, eg algorithms, imply that the user needs access to some sort of technology which may very well be protected by Intellectual property rights. That implies the use of competition law to gain access to such property right, which raises a number of issues and adjustments that need to be made so as to achieve the balance between IP rights and competition that may promote the most innovation¹⁹⁰¹.

In reference to technical de jure standards, there is a general consensus that such standards should be available under FRAND terms. However, the standards now being developed for the IoT in specific and generally for the digital economy are not always collective efforts (de jure standards), rather large system leaders try to develop their own de facto standards. These may not (always) be generally available and the system leaders may claim exclusivity under intellectual property law.¹⁹⁰²

7.3.2.1. A US perspective on access to data and interoperability

Data resembles the assets that refusal to deal jurisprudence in the U.S.A. has considered. The Colgate doctrine represents the starting point, and it empowers traders to select the parties with whom they will deal.¹⁹⁰³ Amazon exercises this right when contracting with the businesses that can sell on its platform. The doctrine logically may restrict the question of data access to entities inside this pool.

Google seeks to rank all relevant sources, although the entities appearing in Google organic search do not choose to deal with Google in a conventional sense.¹⁹⁰⁴ Its business model may expose it to more numerous requests for data.

Businesses selling on platforms could claim that access to data would generate more transactions. They would produce and market their products more effectively. Yet the businesses would utilize the information to increase prices. Platforms have sought to promote the interests of consumers in this respect. Before a court will grant access to data, business users will need to establish that the refusal to deal causes antitrust injury.¹⁹⁰⁵ Less transactions should qualify, and the businesses will use the information to offer better quality products, but they further will be seeking to shift surplus. Where platforms compete in the downstream market, the primary antitrust injury would relate

1901 On these difficult trade-offs, see Ioannis Lianos, *Competition Law and Intellectual Property Rights: Is the Property Rights Approach Right?*, (2006) 8 *Cambridge Yearbook of European Legal Studies* 153.

to ensuring consumers benefit from merit competition, because the platform probably will offer lower-priced and better-quality products.

Existing refusal to deal law additionally requires that the businesses seeking access to data must show a pattern of dealing that the platform ceased, thereby sacrificing revenues to exclude and earn higher revenues later.¹⁹⁰⁶ Amazon has conflicting motives to sell data. It earns a percentage of every sale, suggesting if access to data would boost sales, Amazon would provide it. When a downstream firm runs a business more efficiently than a monopolist could, it will sell more by supporting the distributor.¹⁹⁰⁷

Yet Amazon may refrain from granting access to data because of the potential for price discrimination, which would drive users away from the platform. It also may refrain because granting general access to data at reasonable prices would eliminate the advantage Amazon exploits in those downstream markets where it competes.

Google primarily relies on data to monetize its platform by selling digital ads. It does not offer to sell data apart from those ads.

Forcing platforms to create a market for data by judicial decree would introduce enormous structural changes to digital markets. The essential facilities doctrine has not demanded that monopolists offer goods or services for the sole purpose of strengthening the ability of rivals to compete.¹⁹⁰⁸ The whole point of the doctrine is that they cannot compete effectively without access, or perhaps constrain the monopolist. Effectuating data portability through competition law would create an upstream market to benefit rivals and consumers in all downstream markets. Where granting access to data might jeopardize a platform's business model, courts generally will not order access.¹⁹⁰⁹ This rule about protecting viability would seem to apply more to Google. It could charge less for ads if other platforms could utilize the same information. Yet forcing Google to rank all shopping comparison sites, including its own, by merit does not jeopardize its business model.

Amazon does many things, but it primarily acts as a distributor or retailer. It accounts for about 50 percent of all sales online.¹⁹¹⁰ Amazon should be able to exercise discretion to keep its platform attractive, but that does not conflict with a parallel duty to promote merit competition. Granting access to data in downstream markets where Amazon competes would not weaken its own ability to serve customers. It rather would strengthen the quality of competition.¹⁹¹¹

Competition authorities could force Amazon to bundle data with access to the platform. In other words, they could force Amazon to charge all downstream entities for access to Amazon's data.¹⁹¹² This policy would raise the price to access Amazon's platform and

1906 *Aspen Skiing Co. v. Aspen Highlands Skiing Corp.*, 472 U.S. 585, 603, 608, 105 S.Ct. 2847, 2858, 2860 (1985).

1912 Forcing access has that effect. And "[o]pen access does not mean free access." Spencer Weber Waller & William Tasch,

exclude the possibility of some rivals competing, but it would strengthen competition on the platform. The policy would not necessarily eliminate the issue of pricing: Unless competition authorities say otherwise, Amazon still could choose whether to offer a flat rate or a rate based on willingness to pay.

Pricing data raises all sorts of issues. To justify denying access, U.S.A. courts have focused on the potential for free riding, which lowers efficiency and the incentive to produce.¹⁹¹³ Securing adequate compensation for services qualifies as a universal business justification.¹⁹¹⁴ Should a competition authority isolate the cost necessary to offer data collection? Data analytics? This refers squarely to licensing fees. Should it incorporate a margin that reflects the added value that the data brings to the platform operator, or to competition throughout the platform? Throughout the economy?

Although U.S.A. courts often apply more demanding standards in the context of intellectual property, the FTC has additional options to pursue interoperability. In 2013, the FTC challenged Google's conduct of seeking injunctions based on Standard Essential Patents (SEPs) which it recently had acquired from Motorola Mobility against implementers who were willing to take a license on FRAND terms. The FTC utilized the unfair competition prohibition contained in Section 5 of the FTC Act. Concluding that refusing access to its SEPs on FRAND terms and, hence, obstructing interoperability violated the unfair competition rules, it adopted a consent order. Google agreed to cease the conduct. The consent order states that to avoid violation of the unfair competition rules, Google cannot seek injunctions before making offers to the prospective licensees to conclude a FRAND licensing agreement.¹⁹¹⁵

Drawing on this case, it seems that Section 5 of the FTC Act, in theory, may be utilized by the FTC against platform providers that refuse access to their technology or data if it could be perceived as the standard of the ecosystem, and such refusal prevent interoperability.

7.3.2.2. An EU perspective on access to data and interoperability

To analyse possible antitrust harms in reference to not giving access to data, or to discriminate in giving access to data, from an EU competition law perspective, we need to look at some specific, well-known cases. *Magill*¹⁹¹⁶, *IMS Health*¹⁹¹⁷ and *Microsoft*¹⁹¹⁸ stipulate quite high thresholds for accessing intellectual property, trade secrets and, possibly,

Harmonizing Essential Facilities, 76(3) Antitrust L.J. 741, 766 (2010). If pricing access to data proved unworkable, rate of return regulation could apply. See generally Alan Devlin, *Fundamental Principles of Law & Economics* 378 (2015). The rate of return may capture a portion of the value of analytics.

1913 *Rothery Storage & Van Co. v. Atlas Van Lines, Inc.*, 792 F.2d 210, 212-13 (D.C. Cir. 1986) (Bork, J.).

data held by a dominant firm. They, at least partially, belong to the exceptional circumstance doctrine and indicate that a firm may be granted access to property or even the right to continuously obtain data (e.g., the *Microsoft* case regarding protocol interoperability for the Windows operating system to communicate with back office servers). Indeed, the *Microsoft* case is interesting in this regard, since interoperability is seen as a reason to use competition law to grant access to data. Further, it also relates to leveraging, since the theory of harm includes the notion that Microsoft was leveraging power from the operating systems market, where it was dominant, to the server market, by not giving access to interface information, while using that data for its own server business.¹⁹¹⁹

Interoperability between systems was one of the theoretical cornerstones for testing whether Microsoft's refusal to give interface information to competing server producers could be classified as abuse.¹⁹²⁰ According to the Commission, neither reverse engineering, nor open industry standards, nor the access ensured by the communication licensing programme created in the US, were alternative ways for Microsoft's competitors to achieve product interoperability.¹⁹²¹ Therefore, the Commission stipulated an obligation, later upheld by EU Courts, for Microsoft to supply neutral interoperability information to its competitors on the server market.¹⁹²²

Interoperability could also be demanded in reference to private application programming Interfaces (APIs). Private or privileged APIs might create a strong advantage for services that belong to the same ecosystems, especially when the ecosystem is very large and involves numerous and diverse services. Not being granted access to private APIs implies the risk of exclusion from accessing that and taking advantage of the ecosystem. Ecosystems are connected through APIs, connecting the services. They make the user data accessible only to services from the same ecosystem. If such privileged access to a user's data or connectivity with other services or Internet of Things devices allows a service from the ecosystem to offer a much better product, competitors will not be able to compete on the merits, e.g. based on the best data analytics. APIs can be limited in several ways, and are de facto technical gatekeepers.¹⁹²³

However, when it comes to data, when creating standards for data interoperability it is important to know what form of interoperability and whether the aim is industry-wide horizontal standards or vertical ecosystems unique standards.¹⁹²⁴ As discussed in the EU report for competition policy for the digital era, interoperability can be divided into three levels. Data portability implies the ability of the data subject or machine user to port his or her data from service A to service B. Protocol interoperability ensures that two systems can fully work together and that complementary services can be provided. And finally, data interoperability, which is data portability but with real-time, potentially standardised, access for both the data subject/machine user and entities acting on his or her behalf. Existing data interoperability mechanisms rely on privileged APIs, when a user authorises a service B to access his or her data through service A's API.

Each data owner may organize his data in a way which suits his or her own needs and preferences. Yet, without an agreement or a standard on dataset vocabulary,¹⁹²⁵ an organization might create a barrier for synthesis with other data or for its use by others. Several barriers are relevant. First, one should know what each rubric in a dataset stands for and how exactly it was determined, in order to assess its relevance and reliability. Second, barriers may arise from the way in which the data are organized, even if all parameters are known. This is especially problematic if the database includes numerous parameters or is constantly updated.¹⁹²⁶ Platform interoperability implies, instead, using the same technology standard or platform technology or language, or to make different languages, such as .NET, Java, and C++, interoperate. Indeed, it might be difficult technically to require full interoperability for clouds and data.

As illustrated, the issue whether there might be an abuse when a firm is leveraging an advantage in data to a device market, by exclusively using data, is complex and difficult to judge.¹⁹²⁷ There may be valid business reasons not to give access to data, but anti-competitive effects may appear regardless. This creates uncertainty.

To advance a successful business strategy firms need access to large data-sets, while also be able to efficiently utilize these data-sets. This can only be conducted with data analytics tools, mainly based on software containing algorithms. Algorithms can be basic or advanced, and they may be included of software programmes, implying that they can be protected by copyright protection (cf. eg. the EU Software directive). There are

1924 Björn Lundqvist (2017). Standardization for the Digital Economy: The Issue of Interoperability and Access Under Competition Law. *The Antitrust Bulletin*, 62(4), 710–725. <https://doi.org/10.1177/0003603X17733359>.

1925 Regarding open data in EU, there is now a general consensus to use the DCAT Application Profile for data portals and for describing public sector datasets in Europe. DCAT-AP is a specification based on the Data Catalogue vocabulary. It serves to enable cross-data portal searches for datasets and make public sector data more searchable across borders and sectors. This can be achieved by the exchange of descriptions of datasets between data portals. Many data portals in the EU have implemented DCAT-AP for describing datasets. Please refer to “[Who is using the DCAT-AP?](#)” for an overview of DCAT-AP implementers. <https://joinup.ec.europa.eu/collection/semantic-interoperability-community-semic/dcat-ap#Who is using the DCAT-AP?>, accessed 21 March 2018

several in academia that claims that the bottleneck in reference to the digital economy is not data – multi-homing will provide that data will be available in abundance. The bottlenecks in the data driven industries will instead be connected to the algorithms and data analytics. Others have disagreed, and claim that data analytics and algorithm software are and will be freely available even open source. Nonetheless, irrespective of whether data analytics will be available or not, it is quite clear that access only to data is not enough. Firms need access to ecosystems, IT infrastructure. Indeed, interoperability is the leading focus for upholding competition in the digital economy, and the cases referred to above, especially *Microsoft*, are the most prominent cases under EU Law granting right to access under Competition law. However, inspiration can also be found in the *Huawei* case¹⁹²⁸, that does stipulate a right to license standard essential patents (SEPs), and hence indirectly a right to access infrastructure and dominant interoperability de jure standards. Moreover, there are national cases of interest too, where platform providers have a far-reaching obligation vis-avis users.¹⁹²⁹

Apart from this we also see several legislative initiatives that imply that access should be granted to data, but also to platforms and IT-infrastructure. For example the *eCall* regulation in the European Union. In the preamble, it is stated, that according to Recital 16, “[i]n order to ensure open choice for customers and fair competition, as well as encourage innovation and boost the competitiveness of the Union’s information technology industry on the global market, the eCall in-vehicle systems should be based on an interoperable, standardised, secure and open-access platform for possible future in-vehicle applications or services. As this requires technical and legal back-up, the Com

1928 Huawei Technologies C-170/13 – ECLI:EU:C:2015:477 In *Huawei*, para. 53, the Court states “In those circumstances, and having regard to the fact that an undertaking to grant licences on FRAND terms creates legitimate expectations on the part of third parties that the proprietor of the SEP will in fact grant licences on such terms, a refusal by the proprietor of the SEP to grant a licence on those terms may, in principle, constitute an abuse within the meaning of Article 102 TFEU.” seem to reflect an undelying idea to value interoperability between the different products produced under the relevant technical standard, above the patentees right to exclude. Indeed, it is not a license to all requirement, rather that in principle interoperability should be protected. ‘The interface between EU competition law and standard essential patents – from Orange-Book-Standard to the Huawei case’ in *European Competition Journal*, Volume 11, 2015 – [Issue 2-3](#), 367-401.

1929 For example, the french case, *Cedgedim*, where access to a patient database was tied to the purchase of software for data analytics. *Cedgedim* is a cases regarding refusal to access database, if not the user also purchase the data analytic services. Similarly, the Belgian competition authority adopted in 2015 a settlement decision finding the national lottery body was abusing its dominant position. The lottery was found to have been using its client database, created under its legal monopoly for public lottery, when selling its new sports betting products, in a market where they faced competition. Indeed, the Belgian lottery body was re-using unique data sets on competitive markets. French Competition Authority, Decision n° 14-D-06, dated 08.07.2014, relative à des pratiques. mises en œuvre par la société Cegedim dans le secteur des bases de données d’informations médicales. This decision has been confirmed on appeal but is still pending in front of the Cour de Cassation (the French Supreme Court). See also See the French competition authority’s interim measures decision no. 14-MC-02, of 9 September 2014, concerning Engie, at paras. 289 and 293-294; and the UK CMA’s Final Report on its Energy Market Investigation, dated 24 June 2016, at para. 233 of the summary, and in more detail in paras. 11.64 to 11.66; Koen Platteau, National Lottery settles abuse of dominance case with Competition Authority (29 September 2015), accessed 17 September 2016: <http://www.internationallawoffice.com/Newsletters/Competition-Antitrust/Belgium/Simmons-Simmons/National-Lottery-settles-abuse-of-dominance-case-with-Competition-Authority>

mission should assess without delay, on the basis of consultations with all stakeholders involved, including vehicle manufacturers and independent operators, all options for promoting and ensuring such an open-access platform and, if appropriate, put forward a legislative initiative to that effect. Furthermore, the 112-based eCall in-vehicle system should be accessible for a reasonable fee not exceeding a nominal amount and without discrimination to all independent operators for repair and maintenance purposes in accordance with [...] [author's highlight].¹⁹³⁰

The *eCall* directive seems to lay the groundwork for a future where competitors are able to access data originating from cars used by individuals. The groundwork being that the device should be (connected to) a standardized, secure and open-access platform. Interestingly, the idea seems to be that by creating a standard, competitors will be enabled not (only) to produce *eCall* machines under FRAND licenses, but to actually access *eCall* machines in the cars with their own applications so to pick up Data. Neither the car owner, nor the automobile manufacturers should, thus, have exclusive right to the personal data created in the car (the device), while possibly, need to open up the platform in the car to, for example, leasing firms, insurance companies and independent service providers.¹⁹³¹

The recently updated EU Directive on Payment Services stipulates a right for third parties under certain circumstances to access the banking data of consumers. Consumer should be able to agree that third parties provide services, while accessing consumer bank accounts and internet bank sites. DPS II may, to promote competition, require banks to provide standardized API access to third parties under the auspices of the European Banking Authority (EBA).¹⁹³² This may enable third parties to tailor their banking service towards customers, while using data collected by a competitor. Indeed, it makes the bank platform or even the user interface somewhat open access. Or, at least, it paves the way for it to become open access.

A further EU example, where access and indeed control over data is stipulated differently is the PSI Directive, which regulates that data held by the government should be shared with commercial players under certain circumstances. It creates a leveled playing field when making available Public Sector Information (PSI) as input to a commercial activity, i.e. when the PSI is used as components to new products and services.¹⁹³³ Inter-

1930 Regulation (EU) 2015/758 concerning type-approval requirements for the deployment of the eCall in-vehicle system based on the 112 service and amending Directive 2007/46/EC [2015] OJ L 123/77.

1931 An example of this development could be the AUDI AG, BMW Group, Daimler AG, Ericsson, Huawei, Intel, Nokia and Qualcomm Incorporated, announce 27 September 2016 the formation of the "5G Automotive Association". The association will develop, test and promote communications solutions, support standardization and accelerate commercial availability and global market penetration. The goal is to address society's connected mobility and road safety needs with applications such as connected automated driving, ubiquitous access to services and integration into smart cities and intelligent transportation. https://www.ericsson.com/news/160927-telecommunications-and-automotive-players_244039854_c. Accessed 23 June 2019.

EU Commission, 'A Digital Single Market Strategy for Europe', COM(2015) 192 final.

1933 Green Paper on Public Sector Information in the Information Society, Public Sector Information: A Key Resource for

stinly, PSI Directive stipulates a right for commercial competitors to access data from a public competitor without the need to show dominance on the part of the public entity.¹⁹³⁴

The legislative examples above, all give access more widely and with less of a threshold than the exception circumstance doctrine under Article 102 TFEU. Several of these initiatives give competitors right to access platforms, data and other infrastructure surrounding the digital economy. Indeed, the

7.3.2.3. A BRICS perspective

Brazil: Brazilian Competition Legislation (Law 12,529/2011) provides several tools for competition enforcement in digital markets, when it comes to abuse of dominant position and exclusionary practices. To illustrate, the law explicitly lists among the possible anticompetitive conducts the prevention of rival's access to technology and the abuse of industrial or intellectual property rights (art 36, §3, V and XIX).

Despite having extensive powers to act, CADE has adopted a cautious approach in digital markets. Practice and case law have shown that in very dynamic markets CADE is more concerned about intervening in a market when it should not have intervened (false positive error – over enforcement) than about not intervening in a market when it should have done so (false negative error – under enforcement). CADE investigated alleged anticompetitive restrictions in the contracts of Google's online advertising platform, known as AdWords. After a long investigation with advertisement agencies and sponsors, it concluded that most of the clauses in Google's terms and conditions were not capable of restricting multihoming. According to CADE's GS, clauses that had a restrictive potential could not significantly affect competition in Brazil. Again, the focus was on the lack of actual effects caused by the conduct.¹⁹³⁵

Russia: In Russia, refusal to deal is covered by the paragraph 5 part 1 of Article 10 of the Federal Law "On Protection of Competition" dealing with abuse of dominance. This provision refers to "economically or technologically unjustified refusal or avoiding to enter into an agreement with individual customers" with regard to a specific product or service, and does not directly cover data. Up to date, there is no antitrust case law explicitly referring to refusing or obstructing access to data. However, some cases involve elements of such refusal.

Thus, the decision of FAS of Russia against Microsoft Corporation № 1-00-168/00-11-16 dated 15 August 2017¹⁹³⁶ deals with Microsoft's refusal to provide the antimalware

software developer, “Kaspersky Laboratory”, with the RTM (release to manufacturing) version of the operational system Windows 10 OS within the reasonable timeline, so that Kaspersky could adjust its software to the new version of Microsoft OS. This resulted in failure of Kaspersky to ensure compatibility with the new version of OS and Kaspersky software being disabled on 42% of computers, upon upgrade to Windows 10 OS. In its approach to this case, FAS of Russia focused not on the “constructive” refusal to provide access to RTM version of Microsoft OS (the set of technical information about the final version of OS), but on the creation of discriminatory conditions for the applicant’s antimalware software in comparison with the proprietary antimalware software of Microsoft Corporation – Windows Defender. Apart from obstructing the access to RTM version of Windows 10 OS, FAS of Russia established that Microsoft imposed the higher requirements of access to its OS for external developers (in terms of use of non-documented APIs) than it had for its proprietary software Windows Defender, with the possibility of blocking the external developers from access to Microsoft OS if the their antimalware software uses undocumented APIs.

The analysis of this case shows that the core of Microsoft anticompetitive practices was obstructing access to its platform for external software developers and impeding the interoperability between its OS and external software. This conduct resulted in favouring its own proprietary software, which was not subject to the same requirements. This reveals the similarity between the Russian case and the above EU case *Microsoft v Commission*¹⁹³⁷ that mandated Microsoft to provide neutral interoperability information to its competitors based on the Microsoft’s refusal to provide information which is essential to compete in the market. The remedies applied by FAS of Russia, in fact, were similar to those of the EU Commission: amending Microsoft’s Antimalware Platform Requirements to ensure interoperability with Microsoft OS and providing the access to RTM version of Microsoft OS on reasonable terms. Therefore, this decision aimed at strengthening intra-platform competition allowing external developers to compete effectively in the downstream market of antimalware software.

It is still an open question why FAS of Russia relied on creating discriminatory conditions rather than obstructing access and interoperability as a theory of harm. FAS of Russia has pointed out that “interoperability” was the key in deciding the case at hand hinting on potential “indispensability” of the access to OS to operate in the antimalware products market: “software ability to operate depends directly on compatibility with the operating system which is the “key infrastructure” for the latter”.¹⁹³⁸ The answer might lay in the higher burden of proof for refusal of access cases and the relatively cautious approach in applying this concept to the digital markets.

India: In India, provisions relating to access to data and interoperability do not find mention in the Competition Act, 2002 yet. However, a review of the Competition Act is under

press-center/news/detail.html?id=50521.

1937 Case T-201/04, *Microsoft v Commission*, ECLI:EU:T:2007:289.

1938 FAS Russia ‘Report about the State of Competition in Russian Federation for 2017’, 235, <https://fas.gov.ru/publications/17041> accessed 10 June 2019.

way, and it is recommended that, with the advent of digital economy, network effects as well as control over consumers' data by firms be also included as a criterion for assessing dominance and determining market power.¹⁹³⁹

Separately, a draft Personal Data Protection Bill (PDPB), 2018 has been proposed as a general regulatory framework to regulate access to data. While interoperability *per se* has not been addressed in the PDPB, 2018 it empowers the Data Principals (e.g. consumers) with the Right to Data Portability, which if exercised could tantamount to interoperability of sorts.¹⁹⁴⁰ The draft Bill is yet to be introduced in the Parliament, though.

China: Article 11 of Interim Provisions on Prohibiting Abuse of Dominant Market Positions, which will take effect on 1 Sep 2019, states that an operator's capacity of mastering and handling relevant data may be considered in the establishment of whether an operator hold a dominant market position. In principle, depending on the specific circumstances of the case, the national competition authorities may take into consideration the big data and algorithmic when assessing the market power of the operator in other sectors. Moreover, Article 13 of China's new *Anti-Unfair Competition Law*, which was amended in 2017, stipulates that "operators shall not use network technology or application services to implement actions that affect user selection and interfere with the normal operation of other operators". China's current judicial practice has included "forced opening data interoperability" under the *Anti-Unfair Competition Law*. In the case of "Sina Weibo v. Maimai", the court held that the legitimacy of business models and technical means is not based on innovation and progress, but whether it is in accordance with the general interests of consumers and the interests of the general public. In this case, "Maimai" is a mobile social networking application. Whether its operator TaoU obtains relevant information through collaborative algorithms, consideration of the interests of users should be a priority, instead of relying on technical ability to improperly acquire competition advantage.¹⁹⁴¹ The court finally established the principle of triple authorization. When a third party grabs user data through Open API¹⁹⁴², it needs to obtain "user authorization", "platform authorization" and "user re-authorization"¹⁹⁴³.

This institutional arrangement has a wide range of applicable values and meanings.¹⁹⁴⁴ However, if the data platform, through the Robots agreement, legal statements or technical confrontation intended to restrict interoperability, prohibits others from capturing

1939 CUTS-CIRC Submission to the Competition Law Review Committee, available at: http://www.cuts-ccier.org/pdf/CUTS-CIRC_Submission_to_Competition_Law_Review_Committee.pdf

1940 Section 26, Draft Personal Data Protection Bill, 2018, available at: https://www.meity.gov.in/writereaddata/files/Personal_Data_Protection_Bill,2018.pdf

1941 Xu Ke: "A Triple Approach to Data Protection – Comment on the anti-unfair Competition Case 'Sina Weibo v. Maimai'", *Journal of Shanghai University (Social Science Edition)*, No. 6, 2017, p. 22.

1942 In addition to the Open API, you can also get data through web crawlers or by changing the underlying settings of the operating system.

1943 That is, the user licenses the platform to collect data, and other operators need to obtain the platform license and the user's re-license when acquiring and using the data.

1944 Huang Xiaojin: "Boundary of Competition Law for Data Sharing and Grabbing in the Big Data Era", in *Research on Financial and Economic*, No. 2, 2018, p. 20.

and sharing data in express terms, then the third party will not be able to access or use relevant data timely and effectively even if the consumers have licensed the right of use to the third party. In other words, the data platform maintains its market position by restricting competitors' access to data or preventing data portability and creating barriers to for potential competitors. In this case, restrictions on data interoperability will constitute an exclusionary abuse as prohibited by the *Anti-monopoly Law*, especially when specific data is a key input to support competitors' innovative products or to improve functionality. Such exclusionary abuse may create a blockade effect in the market, inhibit the market entry or expansion of other competitors, or cause other competitors to withdraw from the market, thereby causing competitive damage to data-related markets.¹⁹⁴⁵ By "restricting data interoperability", the practice created an improper competitive advantage.

Concerning the issue of "opening or restricting interoperability", the *Law against Unfair Competition* and the *Anti-monopoly Law* have made different institutional choices based on different value propositions. The former sets forth the prerequisites for "opening data interoperability" through certain technical means, while the latter provides an approach to regulate exclusionary acts of "restricting data interoperability." Therefore, in practice a delicate balance is sought in pursuing values and weighing interest.

South Africa: From a unilateral conduct perspective, the South African Competition Commission has investigated a few cases in reference to the digital economy and none of the cases led to a finding of abuse.¹⁹⁴⁶

7.3.3. (Exclusionary) Discrimination in providing data and search/algorithmic access and net neutrality

7.3.3.1. The many faces of discrimination in competition law

This Section assumes that access to data or algorithms has been provided (a refusal to grant access is examined by a separate section on refusals to supply) and only focuses on discriminatory access to data or algorithms.

Economists consider that a firm price discriminates when two 'similar' products are sold at prices that are different ratios to their respective marginal costs¹⁹⁴⁷. However, it may

1945 Chen Bing: "Identification of the Application of the Abuse of Market Dominance" in China's Anti-Monopoly Law, in Law, No. 1, 2011, p. 92.

1946 See cases such as Entelligence Ltd ("Entelligence") vs Google South Africa and Dirk Lucas vs Microsoft South Africa and others (2009)

1947 GJ Stigler, *The Theory of Price* (Macmillan, 1987). Different marginal costs for 'similar' products may be the result of 'versioning'— for example, a watch offered with strap of different material, more and less prestigious. A narrower definition is that price discrimination occurs where two similar products with the same marginal costs are sold by the same firm at two different prices: see CM Armstrong, 'Recent Developments in the Economics of Price Discrimination' in R Blundell, WK Newey, and T Persson (eds) *Advances in Economics and Econometrics: Theory and Applications*, Ninth World Congress of the Econometric Society, vol 2 (CUP, 2006), ch 4

also apply to non-price discrimination, for instance discrimination on various parameters of quality. Note however that for economists, a simple difference in price of the same product to various customers does not constitute price discrimination if the difference of price reflects a difference in costs—for example, different distribution costs. Price discrimination may be an exclusionary and/or exploitative competition law concern in various circumstances.

With regard to market-distorting exclusionary price discrimination, it is important to distinguish between primary line (or first-degree) discrimination and secondary line (or second-degree) discrimination.

Primary line (or first-degree) price discrimination may involve for instance the implementation of ‘targeted’ predatory pricing (the dominant undertaking implementing selective and predatory price cuts in the customer segment where it faces entry) and mixed bundling or tying strategies in order to exclude the products of its competitors. The foreclosure effects that may arise in these cases relate to the specific conduct giving rise to discrimination, for instance the predatory pricing, the selective price-cutting or mixed bundling, without the need to consider discrimination as a separate type of abuse.

Secondary line (or second-degree) price discrimination raises less competition law concerns, as the discrimination only concerns a downstream market in which the dominant undertaking allegedly committing the abuse is not active. The concern here is that the dominant undertaking should not distort competition on an upstream or a downstream market, as ‘co-contractors of such undertakings must not be favoured or disfavoured in the area of the competition which they practise amongst themselves’¹⁹⁴⁸. The duties such provision imposes to dominant undertakings is particularly interesting if one thinks of the role some undertakings have in controlling or influencing ‘ecosystems’ composed by a number of business partners, and would be competitors, should one also take into account ‘vertical competition’, in particular vertical innovation competition, seriously, and/or vertical exploitation.

A search engine may discriminate against businesses in ranking results. It would discriminate to prompt clicks or purchases—to favour paid ads. The engine has no incentive to effectuate a purchase or click unless it derives from a paid ad. The data that an engine collects could facilitate this objective. It accumulates market data regarding the most popular products related to key words, and Google accumulates individual data relating to past clicks and purchases. After signing into Google, for instance, two customers might find a different ranking of results, also because of their location.¹⁹⁴⁹

From the perspective of competition law, the concern is that the search engine will utilize data or otherwise alter rankings in a manner either that prevents a transaction or that results in a transaction that confers less consumer surplus than that available using

1948 Opinion AG N Wahl in Case C- 525/ 16, *Meo— Serviços de Comunicações e Multimédia v Autoridade da Concorrência*, ECLI:EU:C:2017:1020, para 74.

1949 Mark R. Patterson, *Antitrust Law in the New Economy* 75 (2017).at 75; Maurice E. Stucke & Allen P. Grunes, *Big Data & Competition Policy* 89 (2016) at 188-89.

the platform. Nearly 90 percent of consumers consult search engines prior to buying products or services online or offline.¹⁹⁵⁰

Data may not always serve the best interests of the user. Previous searches or purchases may act as an obstacle to finding the objective during this search. Less innocently, data may enable the engine to entice a user with impulsive purchases related to past purchases or interests rather than to the keywords in this search. Data may permit presenting more expensive items, or any order that deviates from the most relevant answers to the keyword search. Relevance should relate to the best price-quality ratio.

Where a search engine acts intentionally to maximize ad revenue at the expense of transactions or consumer surplus, competition authorities justifiably might adopt some form of strict liability to deter the practice, because of how search engines make money. In a sense this is primary line discrimination, where the system leader discriminate sites or result including competing ads, while promoting result including its own ads. The offense generally will occur on the organic side, by attempting to divert attention to paid ads. Strict liability could affect how the competition authority applied an existing abuse.

Such conduct may fall under different forms of categories of abuse¹⁹⁵¹. In the EU, despite the label of exceptional circumstances, a conventional abuse that also fits this context is a refusal to deal. Ranking prominently in Google organic results, for those entities that belong on the first page, is indispensable to compete, at least online. And competition will not qualify as effective if criteria other than relevance determine organic search results. Rigged markets constitute the antithesis of effective competition. Just 5 percent of consumers look beyond the first page of search results.¹⁹⁵² After establishing intent, the refusal to deal test could resemble a simple tort where plaintiffs would need to show causation and damages.¹⁹⁵³

A less ambitious abuse might relate to a different category of behaviour, a practice that qualifies as primary discriminatory exclusion. A system leader may not generally give access to some business users, while leveraging the power of the platform downstream onto other users' brick-and-mortar markets. The EU *Google shopping* case presents a possible example of this conduct. Discrimination on behalf of the system leaders, in relation to the platform or the data collected, enables a system leader to leverage onto the market of a business user. The platform provider would collect and give access to data or the result of predictive modelling to a specific firm, while refusing access to others, to enable that firm to leverage the data advantage against existing competitors, could be viewed as secondary line discrimination.¹⁹⁵⁴

1954 There are some similar French cases: the French Competition Authority imposed an interim measures to GDF, ordering the gas supplier to grant its competitors an access to some of the consumer data, in particular consumption data, it col-

The dual role of Google, as a digital platform but also a competitor of vertical websites may also be addressed by applying principles deriving out of network neutrality regulation. Network neutrality is an important principle of Internet technology operation, that is, the network provider does not treat the content it transmits differently, and its application in the big data environment is reflected collectively as “search neutrality” and “algorithmic neutrality”.

With the deep development of big data on consumption and the mature development of technologies such as machine learning and algorithm optimization, search engines and algorithms have become more and more “unneutral”. With the user’s past search data and network behavior data, the search engine platform can analyze the user’s search preferences, interest ranges and consumption expectations, select the most relevant web content, and accurately display the appropriate advertisements in the search page. This means that the search results and sorted pages retrieved by the user with personalized keywords have beforehand been subject to the intervention and adjustment of the platform.

The current probes by the EU Commission and the German Bundeskartellamt of Amazon should also be mentioned. According to Competition Commissioner Vestager, DG Comp opened a probe into Amazon’s use of data on its third-party merchants. The idea was to assess the dual role of the e-commerce giant, given that it hosts but also competes against these other merchants. There are concerns that Amazon could be using data about its competitors’ products to its own advantage.¹⁹⁵⁵ It seems that Amazon is using data it collects from its competitors business transaction on Amazon, and use that for setting-up or intensify its own competitive service or product line. Also, third party merchants /business users) seem to be disadvantage in the Amazon ecosystem. The Commission will look into especially issues regarding the use of marketplace data and Buy Box. The subject of examinations conducted by the European Commission will be the standard agreements between Amazon and marketplace sellers, which allow Amazon’s retail business to analyse and use third party seller data. In particular, the Commission will focus on whether and how the use of accumulated marketplace seller data by Amazon as a retailer affects competition. Moreover, the role of data in the se-

lected as a provider of regulated offers (on the gas market). The aim of this interim measure was to allow all suppliers to have the same level of relevant data to make competitive offers to consumers for gas and electricity. (no public information or third party private database existed on households subscribing to gas contracts). French Competition Authority, Decision 14-MC-02 of 09.09.2014. Due to privacy laws, the transmission of GDF data to competitors was conditional to an approval by consumers. A significant share of the consumers did refuse that their data be transferred from GDF to competing operators. The case is discussed in The German and French Competition Authorities joint paper, ‘Competition Law and Data’ (n 1), 20. French Competition Authority, Decision n°13-D-20 of 17.12.2013, confirmed on that points by the court of appeal on 21.05.2015; A similar reasoning has also been used in some merger cases. For instance, in its EDF-Dalkia merger decision. European Commission, “EDF/Dalkia en France”, COMP/M.7137, dated 25.06.2014. 68 French Competition Authority, Decision n° 14-D-06, dated 08.07.2014, relative à des pratiques mises en œuvre par la société Cegedim dans le secteur des bases de données d’informations médicales. This decision has been confirmed on appeal but is still pending in front of the Cour de Cassation (the French Supreme Court).

1955 See the German Competition Authorities press release: https://www.bundeskartellamt.de/SharedDocs/Meldung/EN/Pressemitteilungen/2018/29_11_2018_Verfahrenseinleitung_Amazon.html?nn=3591568

lection of the winners of the “Buy Box” and the impact of Amazon’s potential use of competitively sensitive marketplace seller information on that selection. The “Buy Box” is displayed prominently on Amazon and allows customers to add items from a specific retailer directly into their shopping carts. Winning the “Buy Box” seems key for marketplace sellers as a vast majority of transactions are done through it.¹⁹⁵⁶

On Amazon Marketplace customers can also find many reviews of sellers by other customers (so-called seller ratings) and of products (so-called product reviews or customer reviews). Business users (sellers) consider themselves at a disadvantage in respect of seller ratings because Amazon is not rated as a seller itself. They complain that they face disadvantageous consequences from negative seller ratings (in the presentation of their offers on the website and in the ranking list and the Buy Box) whereas no seller rating is requested after a purchase transaction from Amazon Retail. However, Amazon has asserted that it does not prioritise its own retail business over third-party sellers. The question as to whether reviews can influence the ranking of sellers, including the Buy Box, may possibly also be addressed by the EU Commission’s current inquiry against Amazon.¹⁹⁵⁷

The German probe supplemented the EU Commission probe, and, as stated above, the German Competition Authority analysed Amazon’s terms of business and related practices. The Authority looked into several terms and covenants: liability provisions to the disadvantage of business users, the combination with choice of law and jurisdiction clauses that restricted business users to file complaints against Amazon only in court of law in Luxembourg, the rules on product reviews discriminated business users vis-a-vis Amazon retail business, rule giving Amazon the right to withhold or delay making payment etc.¹⁹⁵⁸ Amazon seemed to have contractually limited its liability vis-a-vis business users in reference to intellectual property infringements, and the standard contract also stipulated far reaching right to terminate business users accounts.¹⁹⁵⁹ Moreover, the standard contract included clauses assigning rights to use the information material which a seller has to provide with regard to the products offered to an extent that business users may not provide a qualitatively better package of product information on their own websites, “quality parity clause”. This will enable manufacturers and sellers to

1959 In 2018 Amazon permanently blocked more than 250,000 seller accounts on its German Marketplace and temporarily blocked over 30,000 accounts. German Competition Authority, Case summary, Amazon amends its terms of business worldwide for sellers on its marketplaces – Bundeskartellamt closes abuse proceedings Sector: Online sales Ref: B2 – 88/18 Date of Decision: 17 July 2019, https://www.bundeskartellamt.de/SharedDocs/Entscheidung/EN/Fallberichte/Missbrauchsaufsicht/2019/B2-88-18.pdf?__blob=publicationFile&v=4

make their own websites more attractive in terms of quality (e.g. images, content) and prevent a potentially stronger pull effect to Amazon Marketplace due to a standardised product description across sales channels. In particular, possibilities to enter into effective competition with large internet platforms on price and quality are to be kept open. The German Competition Authority also made reference to its 2013 proceedings to abolish price parity on Amazon Marketplace in and against the best price clauses of hotel portals (see HRS and booking.com cases) already served this purpose.¹⁹⁶⁰

Amazon agreed however to change the terms and condition and the German Competition Authority closed the investigation, making reference to the upcoming platform to business regulation and that the standard contract by Amazon would need to get amended due to the implementation of said regulation. Indeed, the decision by the German Competition Authority lies in the interface between competition rules and the regulation of unfair contract terms, in reference to business to platform relations, and the Authority seems to be using both interchangeably.

As discussed in *infra*, with big data, certain platforms may be able to exploit customers through price discrimination. By using large datasets and algorithms they may create “almost perfect behavioral discrimination”, which increases overall consumption and profits by exploiting asymmetric information. In the field of algorithm analysis and application, the dynamic pricing mechanism based on machine learning and algorithm autonomous optimization helps enterprises to use data to implement discriminatory pricing. “Big data entraps those who trust it” is a typical example of abuse of big data to implement price discrimination and squeeze consumer surplus.¹⁹⁶¹

7.3.3.2. In-depth EU Perspective on the Google shopping case and Net Neutrality

In a digital economy characterized by zero-prices, the focus has been on other parameters of discrimination than price. The main thrust of this emerging case law is related to the need to ensure the neutrality of the digital platform vis-à-vis the various members of its ecosystem, in particular if it competes with them downstream or upstream. This dual role, for instance platform and retailer, or a search engine and a vertical website (e.g. comparison shopping website, a maps service etc) may establish duties of non-discriminating to an undertaking holding a dominant position. The narratives of ‘search neutrality’ and ‘network neutrality’ convey the importance of the prohibition of discriminatory practices favouring the incumbent’s activities upstream or downstream the value chain in EU law.

As discussed above, the European Commission initiated in November 2010 an investigation against Google’s parent company, Alphabet, with regard to its general search re-

¹⁹⁶⁰ Ibid, 4. Regarding price parity clauses cf. Section XX of E-commerce.

¹⁹⁶¹ In recent years, some Chinese consumers have found that when booking hotel rooms and tickets for taxis and movies through certain online platforms, the prices online are even higher than those they can enjoy at physical front desks; and surprisingly too, the online prices displayed for VIP members are much higher than those displayed for ordinary members. “Is big data entrapping those who have trust in it? Demystifying the True Problem behind the Dispute, in China Youth Daily, March 27, 2017, 9th edition.

sults on its search engine Google. Relying on a large body of evidence, the Commission issued a decision in June 2017 finding that Google has abused its market dominance as a search engine by giving an illegal advantage to another Google product, its comparison shopping service and fining Alphabet €2.42 billion, the largest fine in EU competition law history¹⁹⁶².

Relying on Google's high market shares which exceeded 90 per cent in most countries, the Commission found that Google was dominant in general Internet search markets in all thirty-one countries of the European Economic Area (EEA), since 2008, with the exception of the Czech Republic where it has been dominant since 2011. It was also noted that almost 90 per cent of Google's revenues stem from adverts, such as those it shows consumers in response to a search query, which indicates that the Commission took into account the paying side of the platform, thus connecting market share on the search side with revenues on the advertising side. The Commission also found that there are high barriers to entry in these markets, in part because of network effects, as the more consumers use a search engine, the more attractive it becomes to advertisers, the profits generated being used to attract even more consumers. The Commission also noted the importance of the data a search engine gathers about consumers, which can in turn be used to improve results and thus make the search engine more attractive to them.

Google's abusive conduct concerned the 'separate market of comparison shopping in Europe', to which it first entered in 2004. Its 'Google Shopping' website offered consumers the opportunity to compare products and prices online and find deals from online retailers of all types, including online shops of manufacturers, platforms (such as Amazon and eBay), and other re-sellers. Despite the fact that Google's comparison shopping business' performance was relatively poor, according to the Commission, Google was able to reverse that trend and attract considerable traffic as it began in 2008 to implement in European markets a fundamental change in strategy to push its comparison shopping service. Attracting traffic is, of course, very important, since it brings bigger advertising revenue. The Commission found that this strategy relied on Google's dominance in general Internet search, instead of competition on the merits in comparison shopping markets and apparently involved the following conduct:

- Google has, according to the Commission, systematically given prominent placement to its own comparison- shopping service, its results being displayed at or near the top of the search results.
- Google has allegedly included a number of criteria in its generic search algorithms, as a result of which rival comparison shopping services were demoted in its search results. In contrast, Google's own comparison- shopping service were not subject to Google's generic search algorithms, and thus were not subject to such demotions As a result of these practices, Google's comparison shopping

1962 Google Search (Shopping) (Case AT.39740) Commission Decision (26 June 2017), available at http://ec.europa.eu/competition/elojade/isef/case_details.cfm?proc_code=1_39740

service became much more visible to consumers in Google's search results, whilst rival comparison shopping services were much less visible. As the Commission found evidence showing that consumers click far more often on results that are more visible, that is the results appearing higher up in Google's search results, this being particularly the case on mobile devices given the much smaller screen size, Google's alleged conduct conferred to its own comparison shopping service a significant competitive advantage compared to rivals.

Noting the special responsibility of dominant undertakings not to abuse their powerful market position by restricting competition, either in the market where they are dominant or in separate markets, the Commission found that Google's conduct amounted to an abuse of Google's dominant position in general Internet search. According to the Commission:

'The Conduct is abusive because it constitutes a practice falling outside the scope of competition on the merits as it: (i) diverts traffic in the sense that it decreases traffic from Google's general search results pages to competing comparison shopping services and increases traffic from Google's general search results pages to Google's own comparison shopping service; and (ii) is capable of having, or likely to have, anti-competitive effects in the national markets for comparison shopping services and general search services'¹⁹⁶³.

In conclusion, the Commission seems to focus on both the form of the conduct in question, which consisted in leveraging *and* discrimination, and on its effects on the Google's rivals. The Commission stated that '(a) system of undistorted competition can be guaranteed only if equality of opportunity is secured as between the various economic operators'¹⁹⁶⁴. Although this seems at first sight as aiming to protect competitors, the Commission noting that 'competitors should be able to compete on the merits for the entire market and not just for a part of it', it could also benefit consumers, the Commission also observing that '[c]ustomers and users should have the opportunity to benefit from whatever degree of competition is possible on the market'¹⁹⁶⁵.

In addition to the €2.42 billion fine, calculated on the basis of the value of Google's revenue from its comparison shopping service in the countries affected, the Commission also required Google to stop its illegal conduct within 90 days of the decision and refrain from any measure that has the same or an equivalent object or effect. What is particularly significant is that the decision orders Google to comply with the simple principle of giving equal treatment to rival comparison shopping services and its own service, meaning that 'Google has to apply the same processes and methods to position and display rival comparison shopping services in Google's search results pages as it gives to its own comparison shopping service'¹⁹⁶⁶.

Public authorities have not limited their action in the search engine segment in order to protect vertical websites, such as content providers, which is the most competitive segment of the digital value chain because of the low costs of entry and the absence of natural monopoly characteristics, but have also resorted to regulate the other segment with which content providers are dealing with, the network element (Internet Service providers or ISPs), which presents some natural monopoly-like characteristics, in view of the important fixed costs one needs to incur for the last mile service, plant wiring (or fiber) linking the premises with the content delivery network. Network neutrality (net) policy aims to regulate ISPs and ensure equal treatment of data traffic being transmitted over the internet, prohibiting ISPs from blocking or slowing down of Internet traffic unless this is to comply with a legal order, to ensure network integrity and security, and to manage congestion. The policy is broadly intended to block network operators from gaining an advantage because of the structure of the market (ie their commercial bonds with downstream operators) to affect competition either in the market of reference or in related markets. The principle of net neutrality was enshrined in EU law by Regulation 2015/2120 (also called the Telecom Single Market or TSM Regulation) adopting common EU rules on net neutrality¹⁹⁶⁷. According to these rules, there can be no blocking, throttling and discrimination of internet traffic by Internet Service Providers (ISPs), which effectively denies them the possibility to pick winners or losers on the internet, or decide which content and services are available¹⁹⁶⁸.

Given the inherent vagueness of the TSM Regulation, it has been argued that competition law should be used as an interpretative tool in reaching the objectives set out in the regulation¹⁹⁶⁹. Some authors argue that competition law has the right standards of analysis on how the non-discrimination principle (which stands at the basis of net neutrality) should be conducted, while maintaining the right level of flexibility that *ex ante* regulation is not necessarily concerned with¹⁹⁷⁰. *Ex ante* regulatory intervention would be justified if its benefits outweigh costs; it would be important to avoid a situation where the inability of network providers to obtain a return would reduce their incentive to invest in the network level and infrastructure. *Ex post* competition law would instead allow the network providers to gain the returns (that can then be reinvested on infrastructure) in whatever way they seek, provided this does not distort competition dynamics. Furthermore, it is argued that *ex post* competition intervention will allow further flexibility also on content providers to develop application-level innovation without the constraints of an *ex ante* obstructive non-discriminatory regulation¹⁹⁷¹.

1967 Regulation (EU) 2015/2120 of the European Parliament and of the Council of 25 November 2015 laying down measures concerning open internet access, [2015] OJ L310/1.

1968 For more information on these rules, see ec.europa.eu/digital-single-market/en/open-internet-net-neutrality.

1969 P Alexiadis, 'EU Net Neutrality Policy and the Mobile Sector: The Need for Competition Law Standards' [2016] *Concurrences Review* No. 3 1.

1970 *Ibid.*, 3.

1971 N Angulo Garzaro and A Angulo Garzaro, 'EU competition law and the telecoms single market: network neutrality in the aftermath of the TSM Regulation' (2016) 23 (1) *LESIJ* 40, 44.

There are four points that show that the TSM Regulation would benefit from the guidance of competition law in net neutrality¹⁹⁷²:

Textual references in the TSM Regulation show complementarity between the type of regulation envisaged and competition provisions. The wording in the TSM Regulation of 'agreements' and 'commercial practices' is compatible with the remit of article 101 TFEU and Article 102 TFEU. The strict negative treatment of practices such as blocking and throttling as opposed to other types of traffic management and prioritisation mirrors the by object/by effect distinction envisaged in the competition law regime.

Competition policy intervention in recent years, such as merger control of telecom operators, has shown particular focus and expertise on issues of network capacity and traffic management – key elements in the net neutrality envisaged by the TSM Regulation.

The impartial approach envisaged in respect of bundled services, such as zero-rating practices, is indicative of a view that seeks to eliminate only bundled services that are deemed as market failures rather than bundled services as a whole. In this respect, this approach would suit the competition law narrative with regards to theories of harm and specific types of abuses under article 102 TFEU (such as margin squeezes and tying/bundling) or anticompetitive agreements between Internet Service Provider (ISP) and content providers under article 101 TFEU. In the absence of such issues, there would be no reason to penalise bundled services that have beneficial welfare effects with regards, for example, to customer choice.

It is argued that an *ex ante*, one-size-fits-all, regulatory approach would not work within the emergence of the complex relationships underpinning the Internet value chains. The proliferation of Over the Top ('OTT') operators that are reliant on the infrastructure of ISPs, the presence of significant technology companies such as Google and Facebook, and the increased use of mobile services require a finely tuned analysis that balances competition concerns and welfare gains in the net neutrality arena.

It has been argued that the traditional view of dominating ISPs engaging in blocking or throttling, while originally valid, is shifting to one where power is distributed across all layers of the value chain and significant technology giants are able to exploit ISPs.¹⁹⁷³ Inconsistencies also arise when one does not consider how the competition between ISPs and OTTs is *inter alia* affected by an important factor. The ISPs often bear all the costs of network maintenance and infrastructure used by the OTTs, yet they often are not able to monetise on the additional traffic created by the OTT.¹⁹⁷⁴ The OTTs' upper-hand towards ISPs is also shown by the fact that, irrespective of net-neutrality legislation, the market share of OTTs has increased while eroding the margins of ISPs. Against the idea of the all-powerful ISPs, one could also note the problems ISPs face in the handset device value chain. When dealing against handset makers in this chain, it has been shown

1972 P Alexiadis, 'EU Net Neutrality Policy and the Mobile Sector: The Need for Competition Law Standards' (2016) Conferences Review No. 3 1, 10–11, 19, 25–26, 31.

1973 A Renda, 'Antitrust, Regulation and the Neutrality Trap: A plea for a smart, evidence-based internet policy' [2015] CEPS Special Report No. 104, 6.

1974 Ibid.

that ISPs are unable to retain more profit than handset makers because of the more costly investments to maintain their infrastructure.¹⁹⁷⁵

The arguments above reveal the important interaction between net neutrality and competition law, and the need to take into account the full picture of the modern digital value chains. The Internet's original design has in fact allowed technology giants like Google and Facebook to emerge, and its platformisation has shifted focus to a number of higher layers that are above the original architecture and are formed of a 'patchwork' of multi-sided platforms.¹⁹⁷⁶ Such platforms extract value off the value chains on the basis of different business models and different levels of openness. To this end, it becomes important to think how competition law can engage with the TSM Regulation in light of new technological innovations including 5G mobile broadband systems. These adopt a multi-tier architecture that entails traffic management and prioritisation, and therefore it is not clear the way in which current neutrality legislation would fit in.

A potential option in the application of competition law to the net neutrality landscape could be found in shifting the focus on the value chain, which may offer a great explanatory potential. The OECD has described how there has been a shift from vertical 'all in one' of the traditional telecommunication operators in connectivity, transport, and services, to an uncoupling of these services.¹⁹⁷⁷ Moreover, one can also see a shift in the value chain from a strong geographical and local connection of traditional ISPs (in connection to their physical infrastructure), to more delocalised and globally-oriented players, such as OTTs, that have lower investment necessities with regards to physical infrastructure.¹⁹⁷⁸ The value chain connecting the ISP, OTT and other content providers has already been described, some authors arguing that 'the value of the contribution of each firm is partially dependent on the contributions of other firms' and that '[t]he degree of this value interdependency varies and is not precisely reciprocal'.¹⁹⁷⁹ Indeed, 'in the present context, networks are necessary for all the applications': '[w]hile applications may add value to networks, they are not individually indispensable'.¹⁹⁸⁰

Finally, one can compare the use of IP rights to extract value and the use of IP rights in the digital value chain. Kramer, for example, describes how OTTs (such as Google and Facebook) on higher levels of the value chain 'operate a proprietary virtual network comprised of consumers and data, which is characterized by positive feedback loops that tend to grow large networks even bigger and make entry for alternative providers

even harder.”¹⁹⁸¹ Similarly, proprietary rights include both software and hardware – allowing to extract value thanks to a strategy that interconnects devices, apps and cloud services of the same firm.¹⁹⁸² This combination of smart devices and apps, with cloud storage and processing allows OTT providers to gain wealth of information on end users, thereby extracting value from the chain. The integration of neutrality principles, either in competition law enforcement, or in the context of sector-specific or horizontal regulation, may reduce the likelihood that the control of a bottleneck may lead to abusive discrimination, in particular, but not exclusively, if the dominant undertaking is vertically integrated and competes downstream or upstream with the undertaking that is subject to discriminatory treatment.

7.3.3.3. BRICS

Brazil: Brazilian Competition Legislation (Law 12,529/2011) provides several tools for competition enforcement in digital markets, when it comes to abuse of dominant position and exclusionary practices. On the other hand, despite having extensive powers to act, CADE has adopted a cautious approach in digital markets. Practice and case law have shown that in very dynamic markets CADE is more concerned about intervening in a market when it should not have intervened (false positive error – over enforcement) than about not intervening in a market when it should have done so (false negative error – under enforcement). This conclusion is based not only on Cade’s decisions on cases related to digital markets, some of them presented below, but also on the comparison with the decisions on cases about the traditional industry, for which the Brazilian competition authority has been relatively more restrictive.

Two reasons might be behind this cautious approach. First, CADE considers that in those markets, it is more complex to demonstrate effects and causal links between the conduct and the impact in the market, in other words, there are multiple factors affecting the evolution of the market. Although the legislation is comprehensive enough to allow for intervention without actual effects (ie based on potential effects), CADE has based its actions of abuse of dominance on a careful analysis of effects and justifications. Second, there is a concern with unduly affecting innovation processes. This is particularly important in Brazil, which generally imports technology and is trying to create an environment that can also lead to producing new technologies (at least on the margins).

An example of the cautious approach is the zero rating case. At the request of the Federal Prosecutor’s Office, CADE initiated an investigation against four major telecom companies – Claro, Tim, Oi and Vivo – regarding allegedly anticompetitive conducts due to the practice known as zero-rating (ie not charging data to access certain applications).¹⁹⁸³ Mobile operators were adopting certain business practices in order to allow access to certain websites/apps, without charging the consumer for the data used to access them.

1981 J Kramer and M Wohlfarth, *Regulating Over-the-Top Service Providers in Two-Sided Content Markets: Insights from the Economic Literature*, (2015) 99 3rd quarter *Communications & Strategies* 71, 76.

1982 P Nooren, A Leurdijk and N van Eijk, ‘Net neutrality and the value chain for video’ (2012) 14 (6) *info* 45, 54.

1983 Preliminary Proceedings n° 08700.004314/2016-71.

Examples of the practices were offers of free and unlimited access to Facebook, Twitter, Whatspp, music apps, or free access to certain *apps*. The relevant markets affected were (i) market for mobile cellular services, with four players with similar sizes; and (ii) market for applications and content, dynamic market experiencing intense changes. Cade General Superintendence (GS) considered that there was no exclusive dealing and that those conducts were justified by business reasons. Moreover, the GS evaluated that some of the business offers could actually foster competition and innovation, by allowing consumers to use their data plans to access other websites. The proceedings were dismissed.

The three cases brought against Google have up until now confirmed this trend. In all the proceedings below, CADE General Superintendence (GS) concluded to that there was no evidence of breach of competition law and the cases were sent to the Tribunal to confirm the dismissal (the Google cases are discussed *infra*, but CADE conducted a similar investigation as the eU Commission into Google shopping, however did not identify a causal relationship between Google's conduct and any harm to competition.

Russia: While the Russian Federal Law "On Protection of Competition" does not have any specific provisions related to discrimination in providing data access and net neutrality, the general prohibition of discriminatory practices is established in paragraph 8 part 1 of Article of the Federal Law "On Protection of Competition". As for net neutrality, while there was a discussion on enacting a law on net neutrality in Russia,¹⁹⁸⁴ as of now net neutrality is not officially established in the Russian legislation.

An example of discriminatory practices in providing access to data may be found in the 2017 case of *Microsoft v. Kaspersky*. In that case, there were two main practices that can be considered discrimination in data access on the part of Microsoft.

1) Kaspersky complained about the insufficient time period provided to external antimalware software developers to adjust their software to the RTM (release to manufacturing) version of Microsoft OS. RTM version of Windows 10 can be regarded as the technical data in a broader sense, necessary to ensure compatibility of external software with the OS and its ability to reach the users and compete in the market of antimalware software.

2) Kaspersky complained that Microsoft did not provide its external software developers with the access to certain APIs. In case an external software developer uses undocumented APIs, Microsoft requires a detailed description of such APIs, but does not guarantee support of antimalware software using such APIs. However, as Kaspersky stated, Microsoft used undocumented APIs for its own antimalware software without indicating them and thus gained an advantage over external developers.

The analysis of this case shows that Microsoft used access to its data to gain advantage over developers that provided external software in comparison to its proprietary anti-

1984 "Traffic Without Brakes: the Net Neutrality Principle May Be Recognized in Russia", Kommersant, 6 August 2018, <https://www.kommersant.ru/doc/3706558> accessed 15 June 2019.

malware software – Windows Defender. This is most evident from the second example of discriminatory practices explained above. Microsoft used data in the form of undocumented APIs to significantly limit access to this data to external developers. The remedies applied by the FAS of Russia in this case was aimed at prohibiting this anticompetitive practice: Microsoft was obliged to change its Antimalware Platform Requirements to level off the positions of Microsoft and external developers in terms of antimalware software support.

China: In China, operators relying on big data to achieve human intervention in search engines and algorithm software not only violates the principle of network neutrality, but may also constitute exploitative abuse of consumers prohibited by competition law. Paragraph 1 of Article 17 of China's *Anti-monopoly Law* provides an enumeration of the abuse of market dominance, and Items 1 and 5 under Paragraph 1 provide for exploitative abuse that directly targets consumers. In this type of abuse, operators with market dominance squeeze and exploit consumers through unfair trade, infringing consumers' fair trading rights.¹⁹⁸⁵ Search engines and pricing algorithms perform data interventions to display different product information to different consumer groups. This information, combined with various product parameters such as price and quality, makes it more complicated for consumers to evaluate and compare product information. It is difficult for consumers to identify the recommended content from the natural search results, and it is more difficult to find different pricing strategies for the same product. The behaviors violating search and algorithm neutrality may be identified as differential treatment and pricing discrimination in exploitative abuse.

It is undeniable that accurate advertising and personalized pricing strategies have increased the efficiency of market operations and reduced search and transaction costs for consumers. According to the established framework of China's anti-monopoly law, for regulating conducts concerning "non-neutrality", it is necessary to draw reasonable conclusions with more detailed economic analysis on a case-by-case basis.

India: The Indian Competition Act, 2002 does not specifically entail provisions for discrimination in providing data access, search/ algorithmic and net neutrality. However, barring search/algorithmic discrimination, they do find mention in individual legislations. As mentioned above, the Draft Personal Data Protection Bill, 2018 has been proposed to regulate access to data.

The National Digital Communications Policy, 2018 recognizes the need to uphold the core principles of net neutrality. Further, in July 2018 the Department of Telecommunications approved the net neutrality rules on recommendation of the Telecom Regulatory Authority of India (TRAI).¹⁹⁸⁶ The rules seek to prevent "any form of discrimination or interference" with data, including "blocking, degrading, slowing down, or granting

1985 Chen Bing: "The Coordinated Development of Anti-monopoly Law Implementation and Consumer Protection", in Law, 2013, No. 9, p. 85.

1986 Ministry of Communications, Department of Telecommunications, Networks and Technologies Cell, Regulatory Framework on Net Neutrality, Notification dated July 31, 2018, available at: http://dot.gov.in/sites/default/files/DoT%20Letter%20on%20Net%20Neutrality%20Regulatory%20Framework%20dated%2031%2007%202018_0.pdf?download=1

preferential speeds or treatment to any content” with the exception of being applicable to Internet of Things and Specialised Services.¹⁹⁸⁷ As TRAI enjoys the mandate of promoting a level playing field and facilitating fair competition in the telecom sector, it has the authority to implement provisions of net neutrality.

As regards search discrimination, the Competition Commission of India (CCI or the Commission) analysed the issue in *Matrimony.com Limited v. Google LLC & Ors. with Consumer Unity & Trust Society v. Google LLC & Ors.* (February 2018).¹⁹⁸⁸ In this landmark order, the Commission enforced a fine of \$21 million on Google for search bias and abusing its dominant position in India.¹⁹⁸⁹ The commission observed that Google’s negotiation search intermediation agreements restricted its Indian partners from using similar services provided by competing search engines.¹⁹⁹⁰ The Commission examined these exclusive search intermediation agreements in view of scale and network effects in online search and advertising coupled with Google’s considerable market shares in these markets¹⁹⁹¹. Thus, it was held that Google’s conduct limited its competitor’s ability to scale their operations by extending and preserving its dominance in search intermediations and thereby leading to its abuse.¹⁹⁹²

Further, in *Samir Agrawal vs. ANI Technologies Pvt. Ltd. & Uber* (November 2018), the Commission dealt with unsuccessful allegations of algorithmic price fixing and price discrimination against app-based taxi service providers in India namely Uber and home-grown Ola Cabs.¹⁹⁹³ The informants (complainants) alleged that the algorithmic pricing takes away the agency of riders and drivers to choose the other side based on price competition and are compelled to accept the prices decided by the algorithm.¹⁹⁹⁴ Further, by preventing drivers from competing on prices, Uber and Ola act as trade associations that facilitate a cartel.¹⁹⁹⁵ Additionally, it was also alleged that Uber/Ola use the personalised data of riders to manipulate prices and charge them based on their willingness to pay.¹⁹⁹⁶ However, the CCI rejected all these contentions with reasons and found no anticompetitive conduct or abuse of dominance by Uber and Ola.

South Africa: There has been one case regarding discrimination, also in reference to app-based taxi service, *Metered Taxi Industry vs Uber* (2015)

The complainant was the Metered Taxi Industry which represents the traditional meter taxis. The metered taxi industry alleged that Uber was:

1996 Ibid.

1. conducting unfair business practices in that it secures partnerships with multinational companies and has exposure to their client base ultimately giving it unparalleled market access,
2. non-compliant with the South African public transport rules and regulations in that it does not pay any permit renewal, rank fees and licencing fees as do other traditional metered taxis, and
3. charging below-cost rates to the detriment of traditional metered taxi operators.

The Commission investigated the complaint under abuse of dominance provisions prohibiting predatory pricing. Preliminary findings, during the screening of the complaint found that Uber driver-partners were not charging prices that are below cost in any of the cities in which Uber operated. The Commission decided not to pursue the case to full investigation as the complaint was lodged within one year of Uber commencing its operations in South Africa and it was unlikely to establish anti-competitive effects.

Moreover, the Commission just finalised its the Data Services Market Inquiry.¹⁹⁹⁷ It was initiated by the Competition Commission in terms of Section 43B(2) of the Competition Act No. 89 of 1998 (as amended) in August 2017, in response to a request from the Minister of Economic Development. The initiation of the Inquiry followed persistent concerns expressed by the public about the high level of data prices and the importance of data affordability for the South African economy and consumers. In terms of enhancing price-based competition. The inquiry provisionally identified that existing international comparisons on mobile prepaid data prices collectively indicates that South Africa currently performs poorly relative to other countries, with prices generally on the more expensive end. Moreover, in the mobile industry, the Commission recommends more regulatory scrutiny and potentially action at the wholesale level of the industry in the event there are no voluntary commitments to improve the terms of wholesale access.

7.3.4. Leveraging and Enveloping

7.3.4.1. An economic perspective on leveraging and enveloping

When a company or system leader holds a high-value data asset and has a clear advantage in the relevant data market, tying or bundling in sales can help the company extend its data advantage to the market of the tied product and then profit from the market.

In reference to system leader, it may be useful to instate and prohibit a general form of leveraging abuse achieved by exclusionary or discriminatory use of data. Such leveraging abuse would require identification of the dominant firm, that, by itself or through a proxy, leverages onto a secondary (brick-and-mortar) market by giving itself or a proxy advantages through increased access to data, so that an exclusionary effect on the com-

1997 Competition Commission, Data Market Inquiry Provisional Findings and Recommendations, <http://www.compcom.co.za/wp-content/uploads/2017/09/Data-Services-Inquiry-Report.pdf>

petitive secondary market materializes, or foreclosing an equally efficient existing competitor, by not granting access to said data.

As we have explained in Chapter 4, because of the important network effects, switching costs and the 'winner takes most' dynamics in platform markets, in order to overcome entry barriers, new entrants generally should differentiate their platform, focusing on niche markets, and offer revolutionary functionality to win substantial market share. Taking inspiration from Resource Based View of the firm literature observing that a firm controlling valuable resources in one market may leverage these resources to enter another market that shares use of those resources, some authors argue that a possible way to enter a new platform is to use an 'envelopment strategy'; This consists in one platform moving into another's market, combining its own functionality with the target's, to form a multi-platform bundle and thus aiming to leverage shared user relationships : by foreclosing the incumbent's access to users, entrants are thus able to 'harness the network effects that previously had protected the incumbent'¹⁹⁹⁸. These practices may succeed if the two competing platforms have overlapping user bases and employ similar components¹⁹⁹⁹. Such 'market entry through foreclosure is also viable when bundling platforms that are weak substitutes or are functionally unrelated' (see Figure 7.x.)²⁰⁰⁰. Digital platforms targeted by envelopment may adopt two defensive strategies: open the platform and matching the attacker's bundle (bundle-to-bundle competition).

Figure 7.1.: Envelopment examples (attacker/target)

	Complements	Weak substitutes	Functionally unrelated
Target largely or fully displaced	<ul style="list-style-type: none"> - Windows Media Player/RealPlayer - Windows Explorer/Netscape - Apple iTunes/Odeo - Smartphone/PalmPilot PDA

It becomes therefore important to distinguish between leveraging with the aim to maintain a dominant position (defensive leveraging) or leverage it to an adjacent market of a complement in order to exercise market power (aggressive leveraging), and enveloping practices that may introduce more inter-platform competition. This will require a careful look to the characteristics of the platforms, if there are network effects, user overlap, and the platforms employ similar components.

The Chicago school of economics criticized the leveraging theory by arguing that there is only one monopoly profit to be made, which cannot be increased by tying. The seller cannot earn a double monopoly profit and force consumers to pay even more than what they would pay but for tying. The total amount of restriction that the monopolist may profitably be able to impose being fixed. A monopolist cannot increase prices in a secondary market without losing profits in its primary market, eliminating the incentive to use tying for anticompetitive purposes. The Chicago school advanced that efficiency primarily motivates tying, particularly increased convenience and lower transaction costs.

Although the Chicago School considered that tying might be used to price discriminate, they viewed price discrimination as competitive because it could increase output and total welfare (although it is rather indisputable that it would decrease the welfare of final consumers through a transfer of surplus). However, this was not a concern for the Chicago school of antitrust, which focused on efficiency and total welfare, rather than the welfare of the final consumers, and thus included the additional benefits appropriated by the monopolist through the wealth transfer from the final consumers in their welfare analysis. In addition to increasing tied power, as tying can impair the competitiveness of rivals in the tied market in ways that increase tied product prices and profits, and “increasing tying power” if the tying market is not competitive, tying may lead to “intra-product price discrimination”, in case the buyers use varying amounts of the tied product²⁰⁰¹.

Post-Chicago economists criticized the validity of the single monopoly profit theorem²⁰⁰². They also offered a number of possibility theorems according to which tying may be used in an anticompetitive way. Post-Chicago economists developed a number of stylized models in order to prove that if the tied product market is oligopolistic, and not perfectly competitive, undertakings might have an incentive to leverage their market power from the tying to the tied product market for anticompetitive reasons. They argued a number of reasons/settings that provide an incentive to a monopolist to impose tying restrictions that go beyond cost savings, as described above. If cost savings from joint distribution and production exist, they can be taken into consideration as efficiencies to counterbalance consumer losses, but cost savings are not a necessary cause for a dominant firm to profitably introduce tying and/or bundling. These different models suggest

2002 For a discussion, see E Elhauge, ‘Tying, Bundled Discounts, and the Death of the Single Monopoly Profit Theory’ (2009) 123 Harvard Law Review 397; N Economides, ‘Tying, Bundling, and Loyalty/Requirement Rebates’ in E Elhauge (ed.), Research Handbook on the Economics of Antitrust Law (Edward Elgar, 2012) 121.

that, in certain circumstances, dominant firms may have the interest to deter dynamic innovation that could render obsolete their technological standard.²⁰⁰³ This situation is exacerbated in a network setting, as the dominant firm will have more incentives to engage in exclusionary practices in order to control the standard of the network.²⁰⁰⁴

7.3.4.2. EU and US: comparative perspectives

In the US, there is a general consensus that leveraging is a violation of Section 2 of the Sherman Act, when a firm holding monopoly power uses that power to create actual, or attempt to create, monopoly on a secondary market. When monopolistic leveraging is used in this manner, courts typically agree that it is a violation of Section 2. In other cases, courts have found that leveraging monopoly power in one market to gain – only – a competitive advantage on secondary market may be a violation of Section 2 of the Sherman Act. The division between the courts has triggered a debate among economists whether leveraging of monopoly power to gain economic benefit is even possible.²⁰⁰⁵

In *Berkey Photo, Inc. v. Eastman Kodak Co.*²⁰⁰⁶, from the 2nd Circuit, the monopolistic leveraging doctrine was recognized as a stand-alone claim. The court reasoned that because it was a violation of the Act to use monopoly power to further existing monopolies, it would also be a violation for Kodak to use its market power to achieve a competitive advantage in a second market. The Kodak case caused a split among Circuit courts.²⁰⁰⁷ The Supreme Court addressed the leveraging issue in *Eastman Kodak Co. v. Image Technical Services, Inc.*²⁰⁰⁸ The plaintiff claimed that Kodak used its dominance in the manufacturing of replacement copier parts to gain a monopoly in the market of copier repair. While it was not discussed in the body of the opinion, the Court endorsed the Berkey articulation of the leveraging doctrine. The Court stated that antitrust liability may result when a firm uses its monopoly power in one market “to achieve a competitive advantage in another”. However, the Supreme Court seems to sway. In *Spectrum Sports v. McQuillan*²⁰⁰⁹ decided only a year after Eastman Kodak, the Court expressed a view that appears to contradict its previous comments on leveraging.

Also, in the recent AT&T and Warner merger case²⁰¹⁰, the DOJ based its appeal on challenging the district court’s findings regarding its increased leverage theory of harm.⁸ The

2010 United States v. AT&T, Inc., No. 18-5214, 2019 WL 921544, at *14 (D.C. Cir. Feb. 26, 2019).

DOJ's increased leverage theory was that by combining Time Warner's programming and AT&T's distribution, the merger would give Time Warner increased bargaining leverage in negotiations with rival distributors, leading to higher, supracompetitive prices for millions of consumers. The idea being that Time Warner post merger would be able to get distribution with AT&T and could therefore make a tougher bargain with other distributors, forcing prices go increase. The DC Appeal Court – focusing heavy on the facts – clearly put a heavy burden of DOJ to show facts to substantiate its leveraging claim.²⁰¹¹ The Court of Appeals found the DOJ's arguments "unpersuasive" as a whole.²⁰¹²

In the EU, leveraging is considered relevant often in combination with other forms of abuses, e.g., tying, marginal squeezing or refusal to supply. However, leveraging can be viewed as a broad underlying stand-alone abuse and reference can be made to cases such as *Commercial Solvents*,²⁰¹³ *Telemarketing*,²⁰¹⁴ *TeliaSonera*,²⁰¹⁵ *Teléfonoica*,²⁰¹⁶ and *Microsoft*,²⁰¹⁷ where the conduct analysed is subordinate to the anticompetitive effects created by the dominant firm.²⁰¹⁸

In *Télémarketing* the European Court found also that a leveraging practice may constitute a standalone competition law abuse that could fall under Article 102 TFEU.²⁰¹⁹ The CJEU concluded that notwithstanding the presence of a refusal to deal, an abuse of a dominant position is committed where,

without any objective necessity an undertaking holding a dominant position on a particular market reserves to itself or to an undertaking belonging to the same group an ancillary activity which might be carried out by another undertaking as part of its activities on a neighbouring but separate market, with the possibility of eliminating all competition from such undertaking.²⁰²⁰

The broad approach followed by the CJEU may be explained by the specificities of the case, the dominant position of the undertaking in question, RTL, being due not to the activities of the undertaking itself but to the fact that by reason of provisions laid down by law there can be no competition or only very limited competition on the market.

More recently, the leverage theory has also inspired the recent *Google Search* (Shopping) case of the Commission regarding practices of self-referencing²⁰²¹. It is worth noting that, notwithstanding the fact that the Commission relied on the argument that the loss of traffic from Google's general search results pages represents a large proportion of competing comparison shopping services' traffic which could not effectively be replaced, the Commission framed this case under a standard leverage theory of harm, rather than the more challenging refusal to supply access to an essential facility, or even under a broader theory of exclusionary discrimination under Article 102(c) TFEU. Indeed, the Commission relied on *TeliaSonera* and *Intel* to argue that it is sufficient to establish that Google's conduct was capable of making it more difficult (i.e., short of impossible) for competing comparison shopping services to access their separate but adjacent markets. This hurdle is clearly lower than a requirement to prove that access to Google's general search pages is indispensable, which would have been required had Google's conduct qualified as a vertical foreclosure case akin to a refusal to supply (the *Oscar Bronner* conditions)

The requirements for finding abuse under the monopoly-leveraging concept would then need a finding of two separate markets (data market and device market). The dominant intermediate must adopt a business strategy outside the notion of competition on the merits (right to use, lock-in, non-access to data, non-assert requirement, or discrimination in access to data) on the primary data market. It must subsequently enter onto the (competitive) secondary market or support a proxy's entry. Either entry must cause an exclusionary effect on that market by potentially foreclosing equally efficient, existing competitors. Last, the dominant intermediate must have no objective justification for not giving access to the data.

A leveraging test following the steps above implies that certain features need not be present or, for that matter, identified. The service provided, e.g., the cloud service, does not need to be indispensable, and neither dominance on the secondary market nor elimination of competition on that market need be proven. These steps seem to be set in stone, yet, given that the underlying doctrine of Article 102 TFEU is uncertain, it should be admitted that the steps for a general leveraging test are, by the best estimate, ambiguous.

A third way to recognise not giving access to data as an abuse is to acknowledge that the system leaders are regulators of ecosystems, and that the downstream or connected markets are so-called aftermarkets. When the system leaders' lock-in strategies are so successful, and consumers find it difficult to leave a digital ecosystem, ecosystem-specific aftermarkets can be identified. The relevant yet controversial case in reference to aftermarket is the US Kodak case²⁰²². In that case, Kodak sold copiers, and was recognised as having no market power in that activity but was accused of using its control over Kodak spare-parts to monopolise the market for servicing its copiers. Perhaps, the

2021 *Google Search* (Shopping) (Case AT.39740) Commission Decision, C(2017) 4444 final (27 June 2017), para 339

2022 See the US Kodak case, *Eastman Kodak Co. v. Image Technical Servs., Inc.*, 504 U.S. 451 (1992). For the EU see the Hugin case, *Hugin Kassaregister AB and Hugin Cash Registers Ltd v EU Commission*, Case 22/78, ECLI:EU:C:1979:138

doctrine of aftermarkets can be used also in reference to system leaders collecting data in systems of devices or on platforms, and that controlling an ecosystem would trigger certain special responsibilities in reference to those aftermarkets connected to the platform and the data.

First, an abuse can only be argued if there is some lock-in effects of the customer. In the data economy market definition and the assessment of dominance can be particularly difficult, even more so in the relevant cases of aftermarkets where the initial decision to buy a connected device from an individual supplier may well take place in a competitive environment. Second, it is not necessarily so that the purchaser of a connected device, especially if this is a large industrial customer, suffers from an inferior bargaining position. It may be able to work out the life time price including the after-services.²⁰²³

The remedy for a finding of abuse would be contractual and technical interoperability and data access or that the dominant firm is restricted from accessing and using customers' data. Indeed, utilizing a leveraging test with the view of upholding interoperability for the IoT and access to data tends to increase competition and innovation in the digital economy, and downstream.²⁰²⁴

Demanding a dominant firms to give access or even generally to create a "data common", i.e. access to for all to all data within an ecosystem, would lessen network effects, tipping and the element of central planning, while it would intensify the competition and create efficiencies on after or downstream markets.

This may feel awkward for an efficiency-oriented competition lawyer, because it is akin to industry policy. Nonetheless, for markets plagued with network effects and tipping, protecting data access and interoperability under competition law may be key. Perhaps data access and interoperability can uphold competition to the extent that network effects are prevented and decrease the risk that the legislator will need to create data commons through sector specific regulations.

7.3.4.3. BRICS

Brazil: As stated above, Brazil has up until now been cautious in intervening. The three cases brought against Google have up until now confirmed this trend. In all these proceedings, CADE General Superintendence (GS) concluded that there was no evidence of a breach of competition law and the cases were sent to the Tribunal to confirm the dismissal.

CADE investigated if Google would be unduly favouring its own specific services within the organic results, such as *Google Shopping*, to the detriment of price comparison sites, such as Buscapé, positioning itself in a more privileged area of the webpage (among the sponsored links), something akin to leveraging or tying. The analysis did not lead to a

2023 Josef Drexler, "Data Access and Control in the Era of Connected Devices – Study on Behalf of the European Consumer Organisation BEUC", 2018.

2024 See early discussion regarding the findings by the economists Jens Prüfer and C. Schottmüller, Jens Prüfer and C. Schottmüller, 'Competing with Big Data' (n 72)

finding of violation. Indeed, after an extensive analysis, CADE did not identify a causal relationship between Google's conduct and any harm to competition. CADE also understood that *Google Shopping's* evolution throughout time showed some genuine features of innovation directed to fulfill consumers' and retailers' needs. In this context, CADE's GS dismissed the case.²⁰²⁵

CADE also investigated alleged anticompetitive restrictions in the contracts of Google's online advertising platform, known as *AdWords*. After a long investigation with advertisement agencies and sponsors, it concluded that most of the clauses in Google's terms and conditions were not capable of restricting *multihoming*. According to CADE's GS, clauses that had a restrictive potential could not significantly affect competition in Brazil. Again, the focus was on the lack of actual effects caused by the conduct.²⁰²⁶

Moreover, CADE analysed scraping practices by Google of relevant competitive content held by rival's specific search websites, to use it in Google's own specific search services. It recognised that such practices by dominant companies should be carefully scrutinised. CADE's GS acknowledged that review gathering tools were a relevant asset in the market, but did not find a violation. Indeed, there was not enough evidence of the systematic presentation by Google of content collected from other websites. Also, the conduct would have been irrational as it could not have affected the Brazilian market.

²⁰²⁷

Russia: In Russia, leveraging is not considered as a stand-alone anticompetitive practice.²⁰²⁸ However, there is broader understanding of leveraging as a theory of harm when combined with other anticompetitive practices, such as tying and bundling.

The Google case (decision N 1-14-21/00-11-15 as of 18 September 2015) is exemplary in this respect. In this case FAS of Russia established that Google used its dominant position in the market for pre-installed app stores for Android OS as a leverage in its relations with manufacturers to restrict competition in other markets. According to the EU leveraging test, the Google leveraged its position in one market (pre-installed app stores for Android OS) to enter adjacent markets, such as web search, email, music and video content streaming, etc., which were competitive. It did so through bundling by obliging the manufacturers of mobile devices to pre-install the package of Google apps in order to be able to install Google Play (the product where Google dominated). This created a significant hurdle for developers of competing apps to enter these adjacent markets, thereby causing exclusionary effects.

Apart from bundling, Google engaged in other anticompetitive business strategies, including priority placement for Google applications on the screen of mobile devices, anti-fragmentation requirements and prohibiting the pre-installation of competitors' applications, which can be considered as components of the broader leveraging strategy.

²⁰²⁵ Proceedings 08012.010483/2011-94.

²⁰²⁶ Proceedings 08700.005694/2013-19.

²⁰²⁷ Proceedings 08700.009082/2013-03.

²⁰²⁸ In fact, it is not explicitly mentioned among the list of abusive practices contained in Part 1 Article 10 of the Federal Law "On Protection of Competition", which is not exhaustive though.

Interestingly, FAS of Russia found Google in breach of part 1 Article 10 of the Federal Law “On Protection of Competition” without referring to a specific paragraph, thereby confirming that it is not limited in its analysis to some well-established abusive practices.

In conclusion, FAS of Russia stated that,

Google influences the general conditions of circulation of goods in the adjacent product markets (of mobile applications) due to its dominant position in the market of pre-installed app stores, by creating preferential conditions for its own applications, ensuring that end users prioritise Google applications and, as a result, making monopoly profits in the mobile applications markets.

This summary might serve as an expression of the leverage theory of harm, though not named as such. Probably, in the future, we will witness a broader use of this concept by the Russian competition authority in the digital context.

China: Similar to examining traditional industries in the context of the Chinese anti-monopoly law, to analyze the problem of leveraging by tying in the data field, the first thing to do is to define the “single product”. The issue of a single product in the data market may be as controversial as it happens in the Internet field.

In the case *Qihoo 360 v. Tencent* (for the alleged latter’s abuse of market dominance), the allegation of the plaintiff Qihoo 360 company for Tencent’s tying is that the “QQ software manager” is bundled with the instant messaging software “QQ” and even the “QQ doctor” will be automatically installed when the software “QQ software manager” is upgraded. Qihoo believes that the communication software QQ and the QQ doctor are independent products, and the bundled sales of the two are only a simple superposition of the products, without adding any integration benefits. It’s obvious that the tying/bundling has anti-competitive effects.

The Chinese court adopted a functional standard and claimed that Tencent’s tying practices in this case were anti-competitive. The reason is that the main function of QQ software is instant messaging, which is a separate software product like QQ doctor, QQ butler, security butler and other products.

The most common tying practice in the data market is to bundle the sales of data sets with data analysis software. According to the functional standards established in the previous case, whether there is a functional inevitable connection or a complementary relationship between the product of data set and the analysis service of data, is the key to determine whether the two are independent single products. If the data analysis software provided by other operators in the market can also analyze and process the data set, the bundled sales of the data set and data analysis software may be identified an anti-competitive tying practice. It is sure that in specific cases, the marketing practices and the technical characteristics of the data market need to be taken into account. Perhaps one day in the future, a data transaction that does not include data analysis software may resemble a bicycle with no wheels installed. The so-called tying is no longer valid.

Article 17 of the *Anti-monopoly Law* stipulates that dominant undertakings cannot 5. “Implement[] tie-in sales or impos[e] other unreasonable trading conditions at the time of trading without any justifiable causes.” Although there is some controversy in identifying tying as a common exclusionary abuse, its possible restrictive effect in the data field is still a research priority.

The effect of restricting competition that tying exerts is mainly reflected in the analysis of leveraging. The analysis focuses on the interaction between the two markets, especially on the exclusion and restriction of competition in the tie-in product’s market. Leveraging enables a company to extend its advantage in one market to another, thereby hindering potential competitors from entering the market. With an exclusive collection of data, a company can also raise the costs for competitors, which may result in anti-competitive foreclosure. Moreover, the leveraging reduces the choice and bargaining power of the counterparty.

India: With respect to leveraging in the digital economy, reference can be made to two significant decisions of the Competition Commission of India (CCI). Both the cases revolved around allegations against tech giant Google for violating the Indian competition law. In *Matrimony.com Limited v. Google LLC & Ors.* **with** *Consumer Unity & Trust Society v. Google LLC & Ors.*, the Commission imposed a hefty fine on Google for engaging in search bias and abusing its dominant position in India²⁰²⁹, and recently in *Mr. Umar Javeed & Others Vs. Google LLC & Other*, the Commission ordered investigation into Google alleged anticompetitive conduct of compelling android device manufacturers to pre-install its applications on their devices.²⁰³⁰

In deciding on the former (as discussed above in search bias), the CCI set the tone for its approach in dealing with leveraging by large Internet platforms such as Google.²⁰³¹ It held that *Google is leveraging its strong position in various online search markets to enter into and enhance its position in ancillary market...not only does that cause direct harm to competitors in vertical markets, it also causes direct harm to other website owners...this also harms consumers as they no longer receive the most relevant results*²⁰³².

With respect to the latter decision, the commission observed that compulsory pre-installation of the Google Mobile Services (GMS) i.e. Google’s proprietary applications and services under its Mobile Application Distribution Agreement (MADA) and Android Compatibility Commitment (ACC) agreement signed with android device manufacturers amounts to ‘imposition of unfair condition’ and reduces ‘the ability and incentive of device manufacturers to develop and sell devices operated on alternate versions of Android’, which amounted to ‘prima facie leveraging of Google’s dominant position’.²⁰³³

2033 Competition Commission of India, Case No. 39 of 2018, available at: <https://www.cci.gov.in/sites/default/files/39-of-2018.pdf>

South Africa: South Africa has been cautious in addressing the digital economy. In principle, dominance need not arise in the market where the conduct occurs and it is possible to find a contravention where there is dominance in a related market that is being leveraged into a market where the firm is not dominant.

As to anticompetitive effects, in *Nationwide Airlines (Pty) Ltd, Comair Ltd vs South African Airways (Pty) Ltd* in relation to contraventions of section 8(d) of the South African Competition Act, the Tribunal found that for an abuse to arise it does not require evidence of actual harm to consumers and that evidence of substantial or significant likely exclusion (foreclosure of the market to competition) is sufficient.

7.3.5. Tying & bundling practices

7.3.5.1. An economic perspective on tying/bundling in the digital context

Leveraging is not only a standalone theory of harm but may constitute the main theory of harm in the context of another form of abuse, such as tying or bundling. In the context of digital platforms and data, tying and bundling may appear in fundamental and peripheral services. The most obvious peripheral example consists of Amazon, through its Prime subscription, tying logistics to entertainment. The more fundamental questions lurk in the relationship between platforms, data, ads, and product markets. In many cases, businesses wish to have access to both the platform and the data that the platform records. In some cases, businesses may wish to secure access to the data only. For a tying claim to hold, data and ads must constitute separate products. Whether they do depend on which item the questioner focuses. Digital ads cannot exist apart from data. When a business purchases an ad on a platform, it is buying the data that the platform has collected on users. Businesses are willing to pay more for ads that, because of reliable data, appear before consumers most willing to buy their product at the exact time when those consumers would purchase.

However, the same data exists apart from the ads, even if the platforms do not grant access to it. Businesses, of course, would be willing to pay for data apart from the ads, for use on their own sites, on other platforms, or offline. If demand were strong for data, a platform must have a stronger countervailing incentive not to offer it. Were a platform to untie data and ads, businesses still might buy ads on the platform to reach its many users.

In evaluating a tie of data to ads, U.S.A. courts would apply a technological tying test because of the technological, not contractual, relationship between data and ads. This test looks to market power in the tying product, whether the tie harms competition in the tied market, and to whether efficiencies outweigh anticompetitive effects.²⁰³⁴ The EU examines the same elements, including determining whether separate products and forcing exist. It considers effects under the rubric of anticompetitive foreclosure.

[of-2018.pdf](#)

2034 *United States v. Microsoft Corp.*, 253 F.3d 34, 87 (D.C. Cir. 2001) (per curiam).

The price of buying ads on Google suggests it may have pricing power in both the tying and tied markets. Besides price effects, to identify harm to competition, courts examine the contestability of markets. The relevant tied product, digital ads, would operate across platforms in an expansive market. Yet courts reasonably may question whether consumers are contestable across platforms.²⁰³⁵

In support, Google might constitute the most important restraint on Amazon because it can summon the websites of a multitude of rivals for any of Amazon's downstream products. In opposition, due to Google's importance to offline economic activity and to informational inquiries related to products and services that Amazon does not carry, and to other pursuits, Amazon could not contest many Google users. The platforms utilize different data sets. Nevertheless, where ads or product descriptions on Google and Amazon may overlap, the exchange of data would improve the functioning of markets and produce more transactions.

7.3.5.2. The tying/bundling competition law standards in the EU and the US

In the EU, Article 102(d) provides tying/bundling as an example of an abuse when it subjects to Article 102 TFEU a dominant undertaking when 'making the conclusion of contracts subject to acceptance by the other parties of supplementary obligations which, by their nature or according to commercial usage, have no connection with the subject of such contracts'. The CJEU dealt with contractual tying in two leading cases, *Hilti* and *Tetra Pak II*, which found tying when used by a dominant undertaking an abuse of a dominant position unless objectively justified²⁰³⁶. Both cases concerned tying of consumables tied to a primary product. Contractual tying may also be subject to Article 101 TFEU.

The more recent case law in the United States requires the examination of the anticompetitive effects of the practice before concluding whether there is illegal tying. In *Jefferson Parish*, the Supreme Court adopted a modified per se test for contractual tying.²⁰³⁷ There was a presumption of anticompetitive effects whenever a firm with market power employed bundling practices that had the effect of foreclosing rivals from significant market shares in the tied product market²⁰³⁸, of extracting consumer surplus²⁰³⁹, or of raising barriers to entry in both the tying and the tied markets.²⁰⁴⁰ In comparison to this case law the CJEU position in *Hilti* and *Tetra Pak II* seems to adopt a quasi-per se illegality approach for contractual tying employed by dominant undertakings.

2035 For the importance of contestability to evaluate tying and bundling, see Jay Matthew Strader, Multiple Product Discounts: A Comparative EU/US Competition Law Perspective, 40(3) World Comp. 421, 423, 455-56 (2017).

2036 See, Case C-53/92 P *Hilti AG v EC Commission* [1994] ECR I-667; Case C-333/94 P *Tetra Pak International SA v Commission* [1996] ECR I-5951.

2037 *Jefferson Parish Hosp Dist No 2 v Hyde*, 466 US 2, 12-18 (1984).

2038 *Fortner Enters v US Steel Corp*, 394 US 495 (1969).

2039 *Jefferson Parish*, 466 US 2, 14-15 (market power in the tying market is employed to 'impair competition on the merits in another market', thus 'increasing monopoly profits over what they would be absent the tie').

2040 *Eastman Kodak Co v Image Technical Servs, Inc*, 504 US 451 (1992).

Technological tying was found to constitute an infringement of Article 102 in the EU in the Microsoft I case, where the Commission, confirmed by the General Court of the EU²⁰⁴¹, found that Microsoft had infringed Article 102 TFEU by making supply of its client PC operating system Windows conditional on the simultaneous acquisition of its Windows Media Player (WMP) (*Microsoft I*)²⁰⁴². The Commission found four elements to a tying claim: (i) the tying and the tied products are two separate products; (ii) the undertaking concerned is dominant in the market for the tying product; (iii) the undertaking concerned does not give customers a choice to obtain the tying product without the tied product; and (iv) the practice in question forecloses competition²⁰⁴³.

A few years later, the Commission also opened investigations, following complaints in December 2007 by Opera, the Norwegian Internet browser maker, against Microsoft, sending a Statement of Objection in January 2009, alleging a violation by Microsoft of Article 102 TFEU for tying its web browser, 'Internet Explorer' (IE), to its dominant client PC operating system, 'Windows' (*Microsoft II*).

The Google Android case seems to have been somewhat different, with rather more straight-forward theory of tying as the antitrust harm compared to the *Google shooping* case. The Commission states:

"When Google develops a new version of Android it publishes the source code online. This in principle allows third parties to download and modify this code to create Android forks. The openly accessible Android source code covers basic features of a smart mobile operating system but not Google's proprietary Android apps and services. Device manufacturers who wish to obtain Google's proprietary Android apps and services need to enter into contracts with Google, as part of which Google imposes a number of restrictions. Google also entered into contracts and applied some of these restrictions to certain large mobile network operators, who can also determine which apps and services are installed on devices sold to end users."²⁰⁴⁴

The Commission Android decision concerned three specific types of contractual restrictions that Google has imposed on device manufacturers and mobile network operators which seem to show a general exclusionary business strategy amounting to an exclusionary tying abuse. The restrictions have enabled, according to the Commission, Google to use Android as a vehicle to cement the dominance of its search engine. Thus, the Android operating system was provided with the requirement to install Google search app (and Chrome browser app). In other words, the Commission decision does not question the open source model of the Android operating system as such, however, the contractual restrictions Google imposed. The Commission decision also addressed that Google made payments to certain large manufacturers and mobile network operators on condition that they exclusively pre-installed the Google Search app on their devices;

2041 Case T- 201/ 04, Microsoft Corp v Commission [2007] ECR II- 3601.

and that Google has prevented manufacturers wishing to pre-install Google apps from selling even a single smart mobile device running on alternative versions of Android that were not approved by Google (so-called “Android forks”).²⁰⁴⁵

The EU Google *Andriod* case seems to resemble the classical tying cases such as the *Microsoft* case, while it is still early to discuss the decision since no public version of the decision is yet available. Still it is unique, and has not been followed by similar cases in the US or in the BRICS countries.

7.3.5.3. BRICS

Brazil: as discussed above, the Brazilian authorities have looked into the conduct of Google. Regarding tying, CADE investigated if Google would be unduly favouring its own specific services, such as *Google Shopping*, to the detriment of price comparison sites, such as Buscapé, positioning itself in a more privileged area of the webpage (among the sponsored links). The analysis did not lead to a finding of violation. Indeed, after an extensive analysis, CADE did not identify a causal relationship between Google’s conduct and any harm to competition. CADE also understood that *Google Shopping’s* evolution throughout time showed some genuine features of innovation directed to full consumers’ and retailers’ needs. In this context, CADE’s GS dismissed the case.

Russia: The Russian Federal Law “On Protection of Competition” in part 1 of Article 10 does not explicitly mention tying and bundling in the list of abusive practices prohibited under the Law. This list, however, is non-exhaustive, and both FAS of Russia and Russian case law consider tying and bundling as illegal abusive practices prohibited under part 1 of Article 10 of the Federal Law “On Protection of Competition”.

The Google case (decision N 1-14-21/00-11-15 as of 18 September 2015) illustrates this approach. According to FAS of Russia decision, Google abused its dominant position in the market of pre-installed app stores for Android OS localized for distribution on the territory of the Russian Federation via, inter alia, bundling: (i) Google conditioned installation of Google Play on the mobile devices by pre-installation of other Google Mobile Services (‘GMS’) by manufacturers, including, for example, Google Search, Google Chrome, Gmail, YouTube, Google Drive, (ii) Google imposed on manufacturers the contractual requirement not to install apps of competitors.

FAS of Russia found that Google offered two versions of Android OS for the manufacturers: Android One (pure Android OS with no pre-installed GMS), and Android OS with pre-installed GMS. According to the survey conducted by WCIOM, Russian research company focused on surveys, buyers prefer mobile devices with pre-installed Google Play. Thus, manufacturers need to pre-install Google Play on mobile devices to make them commercially successful.

However, Google required manufacturers to pre-install GMS together with Google Play. FAS of Russia established that there was no technical reason for tying Google Play and

2045 Commission decision of 18 July 2018 in Case AT.40099 – Google Android.

GMS, as each application in GMS might operate separately, therefore, tying didn't have any objective justification.

In connection to direct tying, Google also required manufacturers not to install applications of certain competitors on mobile devices (for example, Yandex Search), thereby ensuring that these providers of the rival applications cannot enter the tied segment of the market of mobile apps and reducing their scale of operation and competitiveness. FAS of Russia concluded that Google abused its dominant position on the market of pre-installed app stores for Android OS.

India: Under the Indian Competition Law, the practices of tying and bundling are prohibited for being anti-competitive. Unlike EU and US, the two practices are distinct from one another in India. Under the Competition Act, 2002, Section 3 and 4 (corresponding to Articles 101 and 102 of the Treaty on Functioning of the European Union) deal with anti-competitive agreements and abuse of dominance respectively.

Section 3(4)(d) of the Indian Competition Act explicitly defines tie-in-arrangements as 'any agreement requiring a purchaser of goods, as a condition of such purchase, to purchase some other goods' thereby excluding bundling from its ambit'.²⁰⁴⁶

Though the Competition Act does not define bundling, the language of Section 4(2)(d) suggests encompassing bundling and reads as 'making the conclusion of contracts subject to acceptance by the other parties of supplementary obligations which, by their nature or according to commercial usage have no connection with the subject of such contracts'.²⁰⁴⁷

The Commission has further recognized the distinction between tying and bundling in the follows²⁰⁴⁸:

There is a subtle difference between the two concepts of tying and bundling. The term "tying" is most often used when the proportion in which the customer purchases the two products is not fixed or specified at the time of purchase, as in a "requirements tie-in" sale. A bundled sale typically refers to a sale in which the products are sold only in fixed proportions. Bundling may also be referred to as a "package tie-in".

The case concerned with allegations against Apple for entering in anticompetitive tying agreements with its distributors that violated section 3(4)(a) of the Act and abuse of its dominant position in violation of section 4 of the Act.

With respect to bundling, although the Commission has discussed the scope of Section 4(2)(d) in various cases to indicate that the section may apply to both tying and bundling allegations²⁰⁴⁹, however in the digital context the Commission recently discussed bun-

2049 Competition Commission of India, Case No. 104 of 2013, available at: https://www.cci.gov.in/sites/default/files/1042013_0.pdf; Competition Commission of India, Case No. 22 of 2010, available at: <https://www.cci.gov.in/sites/>

dling in the proposed combination of Bayer AG and Monsanto (both having large scale operations in the agriculture sector).²⁰⁵⁰ The commission observed that the proposed combination would lead to creation of the largest integrated agriculture company.²⁰⁵¹ The combined entity could then bundle portfolio products of the merging companies thus being able to extract premiums and exhibit a negative impact on consumers and competitors.²⁰⁵² This is likely to have an appreciable adverse effect on competition (prohibited under Section 3 of the Act) in several relevant markets in India.²⁰⁵³ Thus, the commission approved the combination subject to conditions, one relating to bundling being, 'barring the combined entity from offering its clients, farmers, distribution channels and/or its commercial partners, two or more products as a bundle which may potentially have the effect of exclusion of any competitor'.²⁰⁵⁴

China: As discussed above under BRICS leveraging, the problem of leveraging by tying in the data field has been litigated in case *Qihoo 360 v. Tencent* (for the alleged latter's abuse of market dominance), the allegation of the plaintiff Qihoo 360 company for Tencent's tying is that the "QQ software manager" is bundled with the instant messaging software "QQ" and even the "QQ doctor" will be automatically installed when the software "QQ software manager" is upgraded. The Chinese court adopted a functional standard and claimed that Tencent's tying practices in this case were anti-competitive. The reason is that the main function of QQ software is instant messaging, which is a separate software product like QQ doctor, QQ butler, security butler and other products.

A common tying practice in the data market is to bundle the sales of data sets with data analysis software. According to the functional standards established in the previous case, whether there is a functional inevitable connection or a complementary relationship between the product of data set and the analysis service of data, is the key to determine whether the two are independent single products. If the data analysis software provided by other operators in the market can also analyze and process the data set, the bundled sales of the data set and data analysis software may be identified an anti-competitive tying practice. It is sure that in specific cases, the marketing practices and the technical characteristics of the data market need to be taken into account. Perhaps one day in the future, a data transaction that does not include data analysis software may resemble a bicycle with no wheels installed. The so-called tying is no longer valid.

South Africa: As stated above, South Africa has taken a cautious approach to conduct in the digital economy. Tying is however a specific offence under South Africa Competition Act. In order to establish a contravention of section 8(d)(iii) of the Act, which sets out the prohibition against tying: (i) the respondent must be dominant (in the market of the tying product or service); (ii) the dominant firm must sell goods or services on con-

[default/files/Case22of2010OrderMemberGG.pdf](#)

2050 Competition Commission of India, Combination Registration No. C-2017/08/523, available at: https://www.cci.gov.in/sites/default/files/Notice_order_document/Order_14.06.2018.pdf

2051 Ibid.

2052 Ibid.

2054 Ibid.

dition that the buyer purchases separate goods or services unrelated to the object of a contract, or force a buyer to accept a condition unrelated to the object of a contract; (iii) there must be anticompetitive effect in that there is evidence of actual harm to consumer welfare or it results in substantial foreclosure of the market to rivals (*Competition Commission v South African Airways (Pty) Ltd* 18/CR/Mar01); and (iv) the respondent must fail in showing that there are technological, efficiency or other pro-competitive gains which outweigh the anticompetitive effect of that conduct.

It seems likely that a hard tie would be required in order for an abusive tie to be established, although possibly an overwhelming incentive to purchase goods or services together may constitute a constructive tie. Where tying is used to maintain the quality of complementary inputs and to protect the goodwill of firms imposing the tie, it is possible that the conduct may be justified.

7.3.6 Unfair commercial terms and lock-ins

7.3.6.1. Contractual or technical lock-ins

App store contracts, platform agreements, in general, and cloud service agreements may contain potentially anticompetitive clauses. Moreover, several jurisdictions have legal systems that include rules addressing unfair competition. French, German, Japanese competition law, and even the US with Section 5 of the FTC Act, may be used to address unfair commercial terms. One advantage from the viewpoint of the enforcer, is that often unfair competition law stipulates less stringent rules regarding the need to establish dominance, and also in reference to what clauses violate competition law.

In reference to app stores, there are court cases and investigations regarding Apple charging a 30 % commission on app purchases, both in the US and in the EU. The cases in the US currently deal mainly with the issue of standing for purchasers of Apps, while the main trust in the cases is whether Apple can require all apps to be downloaded in the iTunes App Store, with a thereto connected fee of 30 %. App Store Providers beneficial treat their app stores vis-à-vis potential rivals by requiring phone manufacturer to exclusively use their app stores, or by requiring the phone manufacturers to use a package of apps, which neither the manufacturer nor the purchaser of the phone can or allowed to eliminate from the phone.²⁰⁵⁵ In the EU Apple has been accused by Spotify and other app or content providers to discriminate against their apps vis-à-vis competing services or apps that Apple produce by themselves. Moreover, the app stores agreements may contain clauses that restrict the possibility to make apps dependable of other apps. It seems that apple store holders like to prevent that apps develop to platforms for other apps since all apps should be (at least in theory) stand-alone. This prevents the possibility for app producers to create their own ecosystems of apps, connected to a platform app, being the hub of the new ecosystem.

2055 Commission decision of 18 July 2018 in Case AT.40099 – Google Android.

Moreover, platform contract and cloud agreements often do not allow business users to restrict the platform from accessing the data generated by the user or its business, do not allow the user to terminate the agreement, port data to a competing platform, or it may contain overly broad non-assert covenants. Indeed, as discussed above, the services provided by Amazon, Google and other platforms, e.g., transaction site, cloud services, may constitute an example of the problem of few platforms controlling data and possibly gaining market power due to data-driven business model. It is not uncommon that Amazon, Google and other platforms have access to most, if not all, data in their respective ecosystems, while the business users in each ecosystem have limited access even to data generated by them in the ecosystem.

A critical question is whether being a system leader and obtaining data from several participants in a market could amount to holding system market power, while not being active on those markets. Could control of data flows correspond to market power in the ecosystem and thereto connected markets.²⁰⁵⁶ For example, could a system leader having access to data from the majority of the firms active on a downstream market, be considered dominant in the upstream data market or on the product market?

The current probes by the EU Commission and the German Bundeskartellamt of Amazon may soon address issues similar to what have been described above. According to interviews with Competition Commissioner Vestager, DG Comp opened a preliminary probe into Amazon's use of data on its third-party merchants. The idea was to assess the dual role of the e-commerce giant, given that it hosts but also competes against these other merchants. There are concerns that Amazon could be using sensitive information about its competitors' products to its own advantage.²⁰⁵⁷ The German probe seem to be investigating similar conduct, all based on the notion that amazon holds market power.²⁰⁵⁸

The EU commission's *Google AdSense* case should also be mentioned. According to the Commission, Google used exclusivity or relaxed exclusivity clauses to exclude competitors such as Microsoft or Yahoo from third party platforms. Websites such as newspaper websites, blogs or travel sites aggregators often have a search function embedded. When a user searches using this search function, the website delivers both search results and search adverts, which appear alongside the search result. Through AdSense for Search, Google provides these search adverts to owners of "publisher" websites.

2056 See the US Kodak case, *Eastman Kodak Co. v. Image Technical Servs., Inc.*, 504 U.S. 451 (1992), where the Court held that even though an equipment manufacturer lacked significant market power in the primary market for its equipment—copier-duplicators and other imaging equipment—nonetheless, it could have sufficient market power in the secondary aftermarket for repair parts to be liable under the antitrust laws for its exclusionary conduct in the aftermarket. For the EU see the Hugin case, *Hugin Kassaregister AB and Hugin Cash Registers Ltd v EU Commission*, Case 22/78, ECLI:EU:C:1979:138.

2057 See the German Competition Authorities press release: https://www.bundeskartellamt.de/SharedDocs/Meldung/EN/Pressemitteilungen/2018/29_11_2018_Verfahrenseinleitung_Amazon.html?nn=3591568

2058 German Competition Authority's press release Bundeskartellamt initiates abuse proceeding against Amazon, 29.11.2018, https://www.bundeskartellamt.de/SharedDocs/Meldung/EN/Pressemitteilungen/2018/29_11_2018_Verfahrenseinleitung_Amazon.html?nn=3591568

Google is thus an intermediary, like an advertising broker, between advertisers and website owners that want to profit from the space around their search results pages. Therefore, AdSense, which by far the largest firm on the relevant market, works as an online search advertising intermediation platform.²⁰⁵⁹

It was not possible for competitors in online search advertising such as Microsoft and Yahoo to sell advertising space on Google's own search engine results pages. Therefore, third-party websites represent an important entry point for these other suppliers of online search advertising intermediation services to grow their business and try to compete with Google.

Google's provision of online search advertising intermediation services to the most commercially important publishers took place via agreements that were individually negotiated. The Commission has reviewed hundreds of such agreements in the course of its investigation and found that Google first imposed an exclusive supply obligation, which prevented competitors from placing any search adverts on the commercially most significant websites. Then, Google introduced what it called its "relaxed exclusivity" strategy aimed at reserving for its own search adverts the most valuable positions and at controlling competing adverts' performance.

Also the India Competition Commission has analysed exclusivity arrangements in reference to Google Search. In *Matrimony.com Limited v. Google LLC & Ors. with Consumer Unity & Trust Society v. Google LLC & Ors.* (discussed supra),²⁰⁶⁰ the Commission enforced a fine of \$21 million on Google for search bias and abusing its dominant position in India.²⁰⁶¹ The commission observed that Google's negotiation search intermediation agreements restricted its Indian partners from using similar services provided by competing search engines.²⁰⁶² Thus, it was held that Google's conduct limited its competitor's ability to scale their operations by extending and preserving its dominance in search intermediations and thereby leading to its abuse.²⁰⁶³

If the covenants hinder the emergence of innovative technologies, or imply the exclusion of or discrimination against certain firms by preventing their effective access to the result (ie data) of the platform or pool, the competition law prohibition could be triggered.

Technical lock-ins, where a platform provider is able to refuse porting of data on the part of the user for example because data are stored in such a way that porting is impossible or excessively difficult, may be considered a violating of abuse of dominance

2059 Google was by far the strongest player in online search advertising intermediation in the European Economic Area (EEA), with a market share above 70% from 2006 to 2016. In 2016 Google also held market shares generally above 90% in the national markets for general search and above 75% in most of the national markets for online search advertising, where it is present with its flagship product, the Google search engine, which provides search results to consumers.

2060 Competition Commission of India, Case No. 07 and 30 of 2012, available at: <https://www.cci.gov.in/sites/default/files/07%20&%20%2030%20of%202012.pdf>

2061 Ibid.

2062 Ibid.

2063 Ibid.

rules. Such conduct can be anticompetitive, if it implies that a firm is locked-in and excluded or prevented from competing by not being able to access potential customers.

Non-assert clauses are another tool that may be used. Such clauses typically stipulate that the business user is not allowed to assert present or future patents, or other IP rights, against the platform or cloud provider, even if that party infringes said IP rights by, for example, entering the cloud user's core brick-and-mortar market.

Non-assert agreements are normally not considered anticompetitive; on the contrary they can be procompetitive and allow firms to avoid litigation, reduce transaction costs and solve problems arising from blocking patents. The non-assert obligation sometimes extends to third parties designated by a contracting party.

However, non-assert clauses may unreasonably strengthen the position of the platform or discourage innovation by limiting the exclusivity, particularly when the clauses are unlimited in scope or duration, or when their scope is more extensive than the 'value' that the platform or business user obtains by accessing the platform or cloud. Interestingly, internet ecosystem seem almost exempted from infringement litigations. Non-assert clauses have been under scrutiny by competition authorities in a few cases. In 2001, Microsoft was accused of having too wide non-assert clauses vis-à-vis OEMs of computers, implying that Microsoft gained access to all OEMs' hardware patents.²⁰⁶⁴

The more difficult issue is whether an Internet intermediate doubling as a cloud provider may be considered to violate competition law by having a data advantage and leverage that advantage when competing downstream. The advantage in data may originate from a right to access and use customers' data, and such a clause may be considered anticompetitive in certain situations, eg if done in conjunction with violating a data privacy rule (German Facebook case²⁰⁶⁵), or violating sector-specific regulation such as the upcoming P2B regulation.

7.3.6.2. Nonassertion and Nonchallenge Clauses

Although it is generally believed that non-assertion and non-challenge clauses are unique issue of anti-monopoly in the field of intellectual property, the same problem also exists in the digital economy such as big data.

Big data transactions involve large amounts of data, and before they are processed and analyzed, it is difficult to ensure that all data sets have utility value. When dynamic data becomes a transaction object, timeliness is also an important factor in setting data prices. The company might prohibit the licensee from filing a lawsuit claiming rights when its digital analysis software is suspiciously engaged in infringement, or prohibits the

2064 See Microsoft scraps clause in licensing contracts for PC firms. 9 March 2004, Computer weekly, for the EU investigation in 2001, <http://www.computerweekly.com/news/2240054971/Microsoft-scraps-clause-in-licensing-contracts-for-PC-firms>, accessed 21 March 2018.

2065 See German Competition Authority, 'Preliminary assessment in Facebook proceeding: Facebook's collection and use of data from third-party sources is abusive', 19 December 2017, <https://www.bundeskartellamt.de/SharedDocs/Meldung/EN/Pressemitteilungen/2017/19_12_2017_Facebook.html>.

transaction counterparty from challenging the validity of the data in the contract. The non-assertion/non-challenge clause helps the company maintain the “monetizing power” of the data. The market position and power obtained by the data platform with its big data advantage are improperly maintained and strengthened, which in turn causes exploitative damage to the counterparty and consumers.

China has not clearly defined the legal ownership of data, but there are many in the academic circle who believe that electronic data is the expressive or homomorphic structure of information, satisfying the formal requirements of intellectual property objects, and the data set is a new property form of intellectual property. Based on the established framework of China’s intellectual property rights, a new type of rights of intellectual property can be created--- “data right”. In addition, China’s law of IPR, such as *Patent Law* or *Copyright Law*, can provide legal protection for big data. It can be inferred that if the data platform abuses the advantages of big data and impose unreasonable trading conditions to exploit the counterparty and consumers, intellectual property abuse can be determined according to the *Anti-monopoly Law*.

With the non-assertion/non-challenge clause, data holders might use their market advantages to ensure transaction stability and maintain their market interests. But to some extent, it can help to reduce the litigation risk of transactions and enhance the willingness to authorize, thereby increasing the efficiency of data circulation and transactions and exerting a positive impact on consumer welfare. Therefore, in the analysis of the competitive effect of the non-claimed/non-challenge clause, the principle of reasonableness instead of illegality is usually applied.

In China, Article 10 (2) of the *Provisions on Prohibiting the Abuse of Intellectual Property Rights to Preclude or Restrict Competition*, released by the State Administration for Industry and Commerce (SAIC) in April 2015, deals with the issue of non-challenge in the framework of abuse of market dominance. That is, operators with market dominance, without justifiable reasons, may not “prohibit the transaction counterparty from challenging the validity of the data” in the process of exercising intellectual property rights. Article 10 of the *Anti-monopoly Guidelines of the State Council Anti-Monopoly Committee on Intellectual Property Rights*, adopted in November 2018, specifically provides for a non-challenge clause under the section of “monopoly agreement”. The provision reads as follows: “The non-challenge clause means that in the agreements related to intellectual property licensing, the licensor prohibits the licensee to object to the validity of its intellectual property rights”.

In analyzing exclusion or limitation of the market that the clause causes, the following factors can be considered: (1) whether the licensor asks all licensees not to question the validity of the intellectual property rights; (2) whether intellectual property rights involved in the non-challenge clause are licensed for free; (3) whether intellectual property rights involved in the non-challenge clause constitute barriers to entry into the downstream related market; (4) whether intellectual property rights involved in the non-challenge clause hinder the implementation of other competitive intellectual property rights; (5) whether the intellectual property license involved in the non-challenge clause

is exclusive; (6) whether the licensee suffers significant losses due to his challenge of the validity of the licensor's intellectual property rights.

Article 18 (2) of the *Guidelines* also briefly deals with the non-challenge issue in the framework of abuse of market dominance, namely, "prohibition of the counterparty from filing intellectual property infringement suits" is included in the conditions that the operators with market dominance might attach in the transaction involving intellectual property.

The above provisions and guidelines can offer inspiration of thinking and criteria for determination of exploitative abuse and imposing unfair trading conditions in the big data market.

7.3.6.3 Exploitative price discrimination

With big data, certain platforms may be able exploit customers through price discrimination. Collection and processing of customers' data help firms to better understand customers' preferences and design personalized selling strategies. The value of information may not directly be sufficient for first degree price discrimination, yet could lead to "almost perfect" discrimination.²⁰⁶⁶

The issue of perfect discrimination based on big data and algorithms has been widely discussed in academia, with different opinions whether such conduct violates competition law, or not; yet no cases have emerged. Clearly, more personalized pricing can lead to increase in profitability by exploiting asymmetric information. According to one study, Netflix employing a first-degree price discrimination strategy in setting its subscription fee (based on customer's web-browsing information), it would have increased its profit by 12.2%.²⁰⁶⁷

7.3.7. Harm to innovation

Competition Authorities often claim that harm to innovation is harm to competition, even an object restriction of competition, while it is difficult to measure harm to innovation. However, both US and EU antitrust authorities have dealt with cases and claims, where the effect that the authorities and the complainants are purporting is harm to innovation, yet they frame it differently. Generally, these cases deal with industries providing systems, where the dominant firm produces the main component of the system, to which it faces no competition, while it is competing with other firms in the production of auxiliary parts to the main component. The dominant firm pursues thereafter a business strategy where it makes innovative changes to its main component, making it no longer compatible from a technology standpoint with its rivals' auxiliary parts. Is this an antitrust violation, when for example the innovative version of the dominant firms

2066 See Ariel Ezrachi and Maurice Stucke, *Virtual Competition: The Promise and Perils of the Algorithm-Driven Economy* (OUP 2016).

2067 Shiller, Benjamin, (2014), *First Degree Price Discrimination Using Big Data*, No 58, Working Papers, Brandeis University, Department of Economics and International Business School.

component now is closed or not interoperable anymore, or where there is a technology tie with the dominant firm's auxiliary components.²⁰⁶⁸

These cases are often framed as access to technology cases, or exclusionary leveraging, while the business strategy of the dominant firm – predatory innovation – often implies that the firms producing the supporting goods and services are excluded or restricted in their business endeavour. Within the dimension of digital economy, where firms are clustered in ecosystems, scenarios as the above, may very well happen. Interestingly, the Google shopping cases, litigated in several jurisdictions may be addressed from the perspective that the changes Google made to the algorithm (Panda 2.0), which Google claims contained innovation to the benefits of users of Google search, *de facto* lessen competition since competitive website were relegated in the system, while Google's own vertical search sites were not. The Google shopping case is appealed, and it will be interesting to see what the General Court and ECJ will decide on the matter.²⁰⁶⁹

In the US, there has been different views on predatory innovation. Two different lines of reasoning can be depicted under Sec. 2 Sherman Act. Firstly, a dominant firm's implementation of a product change will not be considered anti-competitive when the monopolistic firm can show some degree of innovation or a product improvement.²⁰⁷⁰ No balancing of the benefits of product improvement versus anti-competitive effects shall apply.²⁰⁷¹

In contrast, in *United States v. Microsoft Corp.*²⁰⁷², the Court of Appeals – District of Columbia Circuit has established a different test. Where likely anti-competitive effects are established, the analysis will not end with the defendant delivering its 'trump', *inter alia* an "innovation" or "product improvement defense". Rather, an alleged pro-competitive justification is weighed against any plausible pro- and anti-competitive effects. Indeed, the innovation claim needs to be analysed within the framework of a "balancing enquiry".²⁰⁷³ The US Courts are not in agreement whether to use this test.²⁰⁷⁴

Within the EU, there is no clear test for predatory innovation. Indeed, the Google shopping case can be the determining case for this. As Kerber and Schweitzer claim, a broad

Forthcoming in Jipitec; MAGKS, Joint Discussion Paper Series in Economics, No. 12-2017, 4, available at SSRN: <https://ssrn.com/abstract=2922515> or <http://dx.doi.org/10.2139/ssrn.2922515>. US academics have split along similar lines: Some have argued for a strong presumption in favour of the legality of any type of product innovation, while others have supported the Microsoft balancing test.

er view of the European case law would suggest that the proportionality principle will play a significantly larger role in the EU as opposed to the US, but whether that will indulge the court or not is yet to be seen.

Interestingly, perhaps this line of thinking could be taken further yet. Platforms and ecosystems can be viewed as a specific tight system where the platform is the hub, and all other firms and websites are dependent on the platform and the system leader. It one way it is a joint venture including the participants to collectively develop the ecosystem. It can thus be seen as R&D collaborations, especially given the loose definition of R&D collaborations in several jurisdictions.

A platform or a cloud service agreement that explicitly or implicitly stipulates rules regarding collection, sharing or division in access to data that is used to develop the products and services further. If the collaboration lasts for a period of time and the parties to the agreement hold some degree of market power, rules that imply exclusive access for the system leader (platform provider) to data resulting from the collaboration may risk that competition law is triggered. Indeed, exclusivity clauses, where one party gets access to all data generated by a collaboration with the goal or object to advance the business or to innovate (which is often why firms collect data) may imply that the parties are agreeing not to compete in reference to innovation. That the system leader should innovate on the behalf of the ecosystem, while the other firms will become dependent on the system leader's innovation. Some guidance can be sought in for example the EU R&D block exemption that stipulates that R&D collaborators can not agree that only one party to the agreement should be granted exclusive access to the R&D result (data, know-how, etc.) generated by the collaboration. Such a clause may cause the entire agreement to fall outside the block exemption, i.e. it is considered to be anticompetitive by object under EU Competition law.

There are yet few cases concerning price discrimination using data and algorithms, and academia are somewhat split on the issue.

7.4. Comparative Analysis of Unilateral Exclusionary and Unfair Practices in Data Markets: EU, U.S. and BRICS

In order to seize the opportunities brought about by the digital revolution, all major jurisdictions are committed to the development of the big data industry, including the implementation of reasonable competition law enforcement. In May 2015, the European Commission launched the *Digital Single Market Strategy*. Anti-monopoly law enforcement in the data field is a part of the strategy implementation, aiming to remove legal and regulatory barriers, promote the free flow of data, and advance the cultivation of a unified data market. The access to and use of data are essential in the digital economy environment. To this end, it is necessary to examine market barriers caused by abuses such as data access control, interoperability barriers, and objection of sharing data.

While hosting important inputs to the digital market, the United States has adopted a cautious approach toward large Internet companies or data giants. The approach has

not prevented data giants from obtaining additional economic benefits related to economies of scale and network effects.

By following the principle of prudence, China is actively trying to promote competition law enforcement in the data field. As the fastest-growing economy in the developing countries, China has attached great importance to the big data development strategy in recent years. In 2018, China set up a new market supervision and administration bureau, which has had a positive impact on competition enforcement in the big data arena. At the same time, China's competition law enforcement agencies also stress that China's data-driven market is not yet mature. Technology development and business models have been evolving. Blunt competition enforcement interventions arising from subjective speculations of competition concerns may dampen the enthusiasm of data-driven companies in their innovations of products and business models. It may also undermine innovation-centered competition among operators. China advocates a cautious and science-based competition enforcement in this field.

The European Union and the United States have reviewed several merger cases in the field of big data and investigated the exclusive/exploitative abuses related to the data market. Comparing the competitive law enforcement in the data-driven industry in Europe and the United States, we can see that the law enforcement attitude in Europe is relatively progressive while the attitude in the United States is more conservative. This is partly due to the differences between the legislative norms and law enforcement ideas of the two major jurisdictions.

The EU competition law divides the "abuse of market dominance" into two types, namely, exclusionary abuse and exploitative abuse. This legislative approach shows a propensity of the competition law enforcement agencies of the EU and its member states to focus on market structure performance and social equality. The identification of data-related exclusionary abuses is mainly focused on the investigation of market foreclosure. When improper trading behaviors inhibit the entry or expansion of other competitors, companies with market dominance risk a finding of abuse.

When determining exploitative abuses, more emphasis is put on the consumer. Enterprises that infringe consumer interests or exploit the counterparty in unreasonable terms and conditions, in the process of data acquisition and trading, will be governed by EU competition law.

U.S.A. antitrust law has only recently sought to prioritize data markets, at least partly due to political pressure. U.S.A. antitrust law does rely to a greater extent on the self-correcting potential of markets, and it has focused on effects as delineated by price theory. The EU and U.S.A. further differ on the scope of entry barriers. Even if data qualifies as a key production factor, U.S.A. enforcers will not necessarily view it as an entry barrier.

The differences in regulatory concepts have led to different value orientations in European and American competition law enforcement. The EU believes that more control should be imposed on data-holding companies. By contrast, decisions by the United

States not to act suggest that it has viewed data-holding companies as having exercised viable rights. The agencies have not looked beyond the fact that the data-holding companies have not further increased their market power or charged higher prices to consumers.

Specifically, the differences of competition law enforcement in the two regions are mainly reflected in the following aspects: First, the manifestations of abuse are different. Refusal to supply data may be considered as an exclusionary abuse under EU competition law. If the refusal of the transaction leads to an excessive anti-competitive effect, the EU will utilize the “essential facility” doctrine. The user’s data is an important currency of the data market.

Data-holding enterprises often restrict competitors’ access to data by setting unfairly high prices. To cope with that, a unified data licensing framework should be established through competition law.

In the data field, the United States has never determined that a refusal to trade violates antitrust laws. The “essential facility” principle has limited space for application of competition enforcement practices in the United States. In addition, American law generally does not punish operators for setting high prices. A reason has been that the data market is subject to multi-homing, where consumers move to other suppliers or new competitors enter the market. In conventional markets, multi-homing causes prices to fall rapidly.

Second, the decisions on whether to obtain benefits through unreasonable transactions are different. In the *Google Shopping* case, the European Commission believed that Google committed an abuse of dominance by treating its own shopping comparison website more favorably and lowering the results of competitors. Google asserted several lines of defense: (1) consumers have low conversion costs between different websites (a click away); (2) Google was innovating new forms of algorithms creating consumer welfare, (3) Google is only using the products that are developed by itself without additional market power, (4) No extra prices are paid by consumers. The last two points have caused U.S.A. enforcers to stand down, but the above defenses have not received the support of the European Commission.

Third, there is disagreement on whether “privacy protection should be included in the competition law”. The European Data Protection Supervisor (EDPS) believes that violations of data protection regulations may constitute an exploitative abuse. The German competition law enforcement agency FCO has supported this opinion to a certain extent. By contrast, the attitude of U.S.A. competition law enforcement agencies is more conservative. In the United States, personal data or privacy is an aspect of consumer protection and should not be included in competition law, an official of the FTC said at a meeting. Exploitative behaviours are analysed in Chapter 10.

In view of the exclusionary/exploitative behavior in the field of big data, many BRICS countries still lack clear antimonopoly legal practices. With the exception of Russia which took bold action in the Google Android and Microsoft/Kaspersky Lab cases, they

all have a cautious – hands off – approach towards the digital economy. However, they are quickly engaging and they, respectively, will soon develop their own doctrines.

Indeed, despite having investigated Google and other tech firms, CADE in Brazil has adopted a cautious approach in digital markets. Practice and case law have shown that in very dynamic markets CADE is more concerned about intervening in a market when it should not have intervened (false positive error – over enforcement) than about not intervening in a market when it should have done so (false negative error – under enforcement).

Interestingly, the EU and the Brazilian Google shopping cases show many similarities, while the competition authorities reach different conclusions. The European Commission found that Google when upgrading the algorithm demoted rival comparison shopping services. According to the European Commission, Google upgraded an algorithm (known as *Panda*) to push its rival services to at least page four of the results, while Google's own comparison service was not subject to demoting and had a privileged position in the search result. Inter alia, the demotion of competing services, coupled with the promotion of Google Shopping, led to foreclosure of rivals, and the European Commission found evidence of traffic diversion and alleged causal nexus with Google's conduct.

In comparison, CADE in Brazil was unable to prove that the decrease in traffic of competing service providers was caused by Google's conduct. There was a lack of causal nexus. Moreover, the use of algorithms to demote rivals was considered scarce in Brazil.

However, on a deeper level, it seems that CADE and the European Commission applied different standards for an effects-based analysis. CADE required more evidence of (i) competitive harm and (ii) causal relation with the conduct (closer to an actual effects standard), while the European Commission applied a standard of 'potential effects' (but still going through some important analysis of actual effects). Finally, more weight given by CADE to (i) innovation and (ii) potential efficiencies/justifications in the analysis. The European Commission seems more sceptical of these effects, and tried to weigh them against potential anticompetitive effects.

In China, on January 30, 2019, the SAMR issued the *Prohibition of Abuse of Market Dominant Status (Draft for Comment)*.²⁰⁷⁵ For the first time, it was mentioned in this draft that when considering the dominance of operators of new economic formats including the Internet, it is necessary to consider the factors such as "control of data"²⁰⁷⁶, which is of great significance for data-driven enterprises or data-based business models.

2075 China's State Administration for Markets Regulation: Prohibition of Abuse of Market Dominant Status (Draft for Comment)

2076 <http://samr.saic.gov.cn/gg/201901/P020190130556260418381.pdf>, last access date, February 17, 2019. Article 7 of the "Prohibition of Abuse of Market Dominant Status (Draft for Comment)": The recognition of the operator's dominant position in the market shall be based on the following factors: (6) Other factors related to the determination of the market dominance of the operator. When deciding that new economic operators such as the Internet players have a dominant market status, In addition to considering the paragraph 1 of this article, the following factors should also be taken into account: competition characteristics, business models, network effects, technical features, market innovation, relevant data holding and market power of operators in the relevant market, etc.

Data-related monopolistic behavior has become the focus of competition law enforcement authorities. In the future, it is possible to assess the market power of enterprises through data advantages, and then analyze whether enterprises are abusing advantages of big data to exclude or restrict market competition. From the reality of China, practices on pricing discrimination, interoperability barriers, improper grasping and discriminatory supply in the field of big data may lead the authorities to initiate investigations.

For the first time, data monopoly was included in the scope of China's competition law enforcement. Only principled provisions can be stipulated in legislation. This course will allow China to accumulate relevant experience in law enforcement practices.

FAS of Russia has developed enforcement practice on abuse of dominance by digital companies. However, compared to the relevant enforcement by the EU Commission, the Russian practice is quite limited. Analysis of the cases shows that the Russian competition authority has already addressed issues of providing access to data, tying/bundling and leveraging. At the same time, there are grounds to suggest that FAS of Russia soon will develop its enforcement in the digital sector, because some of the cases are ongoing.

Enforcement practice related to digital giants raised questions of necessity to make relevant amendments to the Russian competition legislation in order to elaborate legal tools to deal with abuse of dominance by players in the digital market. In this regard, FAS of Russia prepared a draft text of amendments to the Federal Law "On Protection of Competition" (so-called the 'Fifth antimonopoly package'), which includes specific provisions on abuse of dominance. They reflect FAS of Russia's intent to add to Article 10 (Abuse of Dominant Position) of the Federal Law "On Protection of Competition" a provision on discriminatory access to data. Discussion on proposed amendments is very intense. It involves both public authorities and competition and digital experts.

In several aspects the South African approach mirrors the Brazilian, while the India Competition Authority has delivered decision and initiated an investigation into the conduct of Google.²⁰⁷⁷ From a unilateral conduct perspective, the South African Competition Commission has investigated a few cases and none of the cases led to a finding of violation. However, given the nature of the digital markets South Africa, has benefited from positive externalities arising from prosecutions in other jurisdictions (eg. global remedies in the Google case).

Indeed, all BRICS countries initially had a hands-off approach, and are now initiating more in-depth analysis of the digital economy and the large firms active in the digital economy.

A common thread in several of the investigations in the BRICS countries, as well as in the EU, is the theory that platform providers use powerful platforms to leverage power to other neighbouring markets. Here a common methodology could be pursued. In several jurisdictions, Google has been found to use its dominant position, ie platform (for example Google App store or Google search), to leverage in to other businesses.

²⁰⁷⁷ See *supra*.

Few researchers claim that such conduct will lessen in the future. On the contrary, leveraging in the digital economy will probably increase when data becomes a more prominent tool for competition, and when data and data analytics may be used. There will be more global networks and systems also in reference to brick-and-mortar products, eg. smart kitchens etc, with system leaders. The connected network industries invites systems and system leaders to develop, and conducts such a leveraging. Interoperability services migrate towards single solutions.

It is interesting to note that Competition authorities both in the BRICS countries as well as in the EU have identified firms as dominant in reference to search and other services provided in the digital economy using rather straight forward analysis taking into consideration the number of users and network effects etc. Given the discussion in this chapter, a line of reasoning that could be pursued is that dominance in reference to the digital economy, and, specifically, in reference to certain platforms could be based on a direct analysis of the service provided by the platforms, and the interaction between the platforms, respectively, and the ecosystems surrounding them. The platforms of today in several aspects generally provide the service of interoperability to the users. They provide matching service and connect users and producers, with thereto service of identifying likely purchasers and/or best choice of product or service. There is a general consensus among many in academia that interoperability services and technologies are plagued by network effect often migrate towards one solution.²⁰⁷⁸ Interoperability technology or services migrate towards one solution since network effects commands that the efficient solution is to have one service for the network. To some extent, they reflect infrastructure, similar to the 5G telecommunication technology, railways, etc. At least if the solution is able to create network effects and, the platform-service wins and tips the service market in its favour. Certain Internet services could hence be identified as an infrastructure type of global services, with thereto connected responsibilities for providing global infrastructure.

2078 It has been claimed that the information economy is populated with temporary monopolies. Hardware and software firms hold monopolies today knowing that a new technology will emerge that will topple their technology and, thus, overtake their monopoly position. In comparison, the industrial economy was, and still is, populated by stable oligopolies. The central difference between these two economies is that they have fundamentally different approaches to being successful: the driver in industrial economics is economy of scale, while the driver for the information economy is network effect. Network effects are now an old idea. Several researchers have discussed this. See Carl Shapiro and Hal R. Varian, *Information Rules* (Harvard Business School Press 1999), 173 et seq. See also Neil Gandal, 'Compatibility, Standardization, and Network Effects: Some Policy Implications', (2002) 18 *Oxford Review of Economic Policy*, 80; Michael Katz and Carl Shapiro, 'Systems Competition and Network Effects', (1994) 8 *Journal of Economic Perspective*, 93; Mark Lemley and David McGowan, 'Legal Implications of Network Economic Effects', (1998) 86 *California Law Review*, 479; Michael Schallap, 'The IPR Paradox: Leveraging Intellectual Property Rights to Encourage Interoperability in the Network Computing Age', (2000) 28 *AIPLY Quarterly Journal*, 195. For definitions of network industries and tipping, see Michael Katz and Carl Shapiro, 'Systems Competition and Network Effects', (1994) 8 *Journal of Economic Perspective*, 93, 105 et seq.; Mark Lemley and David McGowan, 'Legal Implications of Network Economic Effects', (1998) 86 *California Law Review* 479, 500 et seq.; and Mark Lemley, 'Intellectual Property Rights and Standard-Setting Organizations', (2002) 90 *California Law Review*, 1889, 1896 et seq.

Moreover, the platform markets – irrespective of hosting an infrastructure type of service or not – can, when tipping has occurred, can be defined as ‘failed’. When network effect has been able to tip the market in the favour of one service, the system leader providing that service has then gained the position of winner takes most of the platform market, and becomes the regulator of that ecosystem, implying special responsibilities to foster and uphold competition on downstream, upstream and on aftermarkets in the ecosystem. When markets have failed, competition law should be utilized to create competition ‘within’ the market, i.e. the connected ecosystem, rather than ‘for’ the platforms market.

The above analysis can possibly be conducted without the need of in-depth analysis of the fluid platform markets for attention (inter-platform competition), and could be a more straightforward analysis, focusing on whether the service provided on the relevant platform has tipped and the problems platforms create within their respective ecosystems (intra platform ecosystem). Thus, system leaders could be regarded as holding power in relation to the services provided or ecosystems without a finding of having power in platform-to-platform competition. The conclusion would be that platforms providing these services should be regarded as regulators of said ecosystems and networks. There will be little if no competition for the platforms and the system leaders, respectively, therefore have special responsibilities to create levelled playing fields in their ecosystems.²⁰⁷⁹ This could imply far-reaching responsibilities for system leaders in ecosystems.

In reference to abuse, several jurisdictions focus on leveraging, while also identifying that the contracts between firms in the ecosystems may very well include exclusivity or semi-exclusivity clauses. The abuses seem to be centred around platforms. Platforms may be used to favour or discriminate to the benefit of affiliated or directly owned firms in downstream, neighbouring or upstream markets. Indeed, platforms that have gained leading positions in the ecosystem have the power to exclude competitors or to lock-in customers or business users. In addition, their control and use of data regarding their customer and users, and their financial resources contribute to their leading roles within their respective networks vis-à-vis business users.²⁰⁸⁰ They may exploit customers and business users by utilizing business strategies of, for example, personalised pricing, and exploitative tying, or by just knowing so much more about the customers of their competitors. However, are they seen as regulators the system leaders then need to treat its business users under something akin to FRAND terms. The business users should be able to use the ecosystem on fair, reasonable and non-discriminatory terms. Has a system leader for example granted access to data to a firm in the ecosystems (subsidiary, affiliated firm or third party) on certain terms, also other firms in the ecosystem could have a right to access such datasets on something similar to FRAND terms.

2079 Jacques Crémer, Yves-Alexandre de Montjoye, Heike Schweitzer, Competition policy for the digital era, Final report, 2019, 69 et seq.

2080 Rupprecht Podszun, (2017) Innovation, Variety & Fair Choice – New Rules for the Digital Economy: Expert Opinion for Finanzplatz München Initiative (FPMI). Available at SSRN: <https://ssrn.com/abstract=3243403> or <http://dx.doi.org/10.2139/ssrn.3243403>

To address the issue of platform-to-platform competition, we need to use general competition law to regulate the underlying conduct that triggers indirect (or direct) network effects and tipping, so to prevent monopolies to be created, while still not kill the incentive for firms to pursue platform-to-platform competition. Moreover, the issue is whether we should turn on the firms that gain monopoly position due to indirect network effect and tipping. They have in one sense used economy of scale to gain this position. Yet, economy of scale on digital markets does not necessarily imply lower prices or for that matter greater efficiencies. Moreover, we know that the firms that have tipped digital markets and gained market power will most likely hold on to their position because it is very difficult to break a monopoly built on indirect network effect.²⁰⁸¹

In the United States, leading politicians have in light of the power of platforms and in relation to platforms participating as sellers on their own platforms call for the break up some technology companies.²⁰⁸² Also participants in academia have expressed similar views.²⁰⁸³

A less intrusive way also suggested in the EU Commission report 'Competition policy for the digital era', to resolve the issue of whether using network effect and tipping to gain monopoly would amount to an abuse, is to utilize the principle of special responsibilities: that when a platform driven by indirect effect has been established, the system leader controlling the platform is allowed to continue having the platform, yet should be considered the regulator of the connected ecosystem or network. There will be little, if no, competition for that network or ecosystem and the system leader therefore has a special responsibility to create competition by creating a levelled playing field for downstream and connected markets, similar to that of a regulator.²⁰⁸⁴

When a system leader has obtained the status of regulator of its ecosystem a higher degree of responsibility would be applicable. A regulator needs to be fair, reasonable and apply principles of non-discrimination. Indeed, a multitude of conduct may be considered per se abuses, depending on where to draw the line and what effects need to proven: preventing interoperability, access to ecosystems or IT-systems and preventing portability of data, would be considered abuses or monopolisation under such higher degree of responsibility. Indeed, system leaders may have an obligation to welcome business users to its ecosystem, and treat them somewhat equally. Discrimination, by

not creating a levelled playing field, or by not displaying similar business users, on equal term, in search results or on product/services comparison sites may be an abuse. Several of the issues raised in this chapter could be considered a violation under the wrong circumstances. Indeed, competition law could when treating system leaders as regulators create something akin to platform neutrality, similar to Internet neutrality.

Chapter 8: Algorithmic Collusion and Competition Law

Ioannis Lianos, Evgenia Montchenkova & Ekaterina Semenova with Hamid Ekbia and the BRICS teams

8.1. Can computers/algorithms collude or facilitate collusion?: setting the parameters of the problem

For many decades now, questions of a general form about the capabilities of AI systems have been asked by scientists, philosophers, engineers, business people, politicians, and even laypeople: “*Can computers do X?*,” where X varies depending on who is asking the question and when they are asking it. The scientific- and philosophically minded inquirer, for instance, finds in AI an effective tool for a scientific psychology that would explain how human minds work. To this group and early on, X stood for mental capacities such as “think,” “understand,” and “communicate,” while in later decades it represented “feel,” “socialize,” and “empathize.” The seminal paper by Alan Turing (1950), which starts with the question “Can computers think?” can be considered the founding moment of this brand of “scientific AI.”²⁰⁸⁵

Pragmatically minded engineers, artists, professionals, and entrepreneurs, on the other hand, ask more practical questions, having to do with particular feats: “Can computers prove theorems? Can they recognize faces? Can they tell the difference between an explosive mine and a rock deep down in the ocean? Can they develop expertise as a doctor or a chemist? Can they play chess, compose music, make paintings, or translate between languages?,” and, more recently, “Can they drive cars? Can they predict future criminals? Can they identify good job applicants?” The General Problem Solver (GPS) developed by Allen Newell and Herbert Simon provides a first example of this brand of “engineering AI.”

These two sets of questions represent two brands of AI, the tension between which has defined the tumultuous history of the field, driving it through summers of enthusiasm and winters of skepticism²⁰⁸⁶. Throughout the decades, these two brands have lived a tense marriage together, but a consistent trend has pushed the early scientific aspirations to the sidelines, bringing business and engineering ambitions to prominence. While the tension is still somewhat present, one can safely declare engineering AI, with a strong flavor of entrepreneurship, as the ultimate winner at this moment. The rise of Big Data and machine learning techniques under the rubric of AI has provided ample

2085 Whether or not Turing himself had a scientific goal in mind is a point of contention (Dennett 1990/2004), but that a group of AI practitioners conceived computers as research tools for a proper science of psychology is hardly debatable.

2086 See, H.R. Ekbia, *Artificial Dreams – The Quest for Non-Biological Intelligence* (CUP, 2008).

ammunition for this final victory, allowing engineers and entrepreneurs to accomplish awe-inspiring but, at the same time, disconcerting goals and milestones in areas such as stock trading, bidding, and algorithmic pricing. It is in a moment like this that legal scholars and practitioners have joined the fray, asking questions such as, “Can computers price discriminate? Can they identify monopolistic behavior? Can they collude?”

The possibility of collusion by algorithms (or algorithmic collusion) has become a topic of intense debate among scholars and practitioners of antitrust law in recent years²⁰⁸⁷. Ezrachi and Stucke have observed with regard to the impact of artificial intelligence to collusion:

‘Computers may limit competition not only through agreement or concerted practice, but also through more subtle means. For example, this may be the case when similar computer algorithms promote a stable market environment in which they predict each other’s reaction and dominant strategy. Such a digitalized environment may be more predictable and controllable. Furthermore, it does not suffer from behavioral biases and is less susceptible to possible deterrent effects generated through antitrust enforcement’²⁰⁸⁸.

The authors note ‘four non- exclusive categories of collusion— the “Messenger”, “Hub and Spoke”, “Predictable Agent” and “Autonomous Machine”’. According to Ezrachi and Stucke, ‘*Messenger*— concerns the use of computers to execute the will of humans in their quest to collude and restrict competition’; ‘*Hub and Spoke*— concerns the use of a single algorithm to determine the market price charged by numerous users’; ‘*Predictable*

Agent— presents a more complex scenario', in which 'humans unilaterally design the machine to deliver predictable outcomes and react in a given way to changing market conditions', however, 'with awareness of likely developments of other machines used by its competitors' and finally the '*Autonomous Machine*' where 'the competitors unilaterally create and use computer algorithms to achieve a given target, such as profit maximization', the machines, 'through self- learning and experiment', determining 'independently the means to optimize profit'²⁰⁸⁹.

Furthermore, there have been some concerns raised with regard to digital assistants, such as Watson, Deepmind, Alexa, or robo- selling to increase the power of oligopolists to charge supra- competitive prices²⁰⁹⁰. Artificial intelligence (AI) may facilitate coordination between a large number of sellers, providing them a long- term perspective on their profits, rather than a short-term one that would provide them incentives to cheat, and could also enable a more effective monitoring of the collusive outcome, as AI may be able to identify the real causes of price decreases. AI and Big Data may also augment the anti- competitive strategies by combining different sources of information (and not just price), predicting the rivals' cost curves and establishing with greater accuracy what would be the optimal strategy in the specific market circumstances. However, the ability of discriminating between different groups of consumers, or even offer personalized pricing, may lead to products that are less homogeneous, may increase product differentiation, and consequently reduce the risks of price transparency and collusion²⁰⁹¹.

Finally, the emergence of blockchain technology also raises interesting issues as to its impact on collusive activity.

Although these concerns are plainly justified, one may reformulate the original question — "Can computers collude?" — to the more pragmatically oriented question, "What would it take for computers to be able to collude?," or put differently, "What are the conditions of possibility for computers to be able to collude?" Such conditions, can be social, economic, cultural, technological, or, as is often the case, a combination of these.

2089 Ezrachi and ME Stucke, 'Artificial Intelligence & Collusion: When Computers Inhibit Innovation' [2017] University of Illinois L Rev 1775, 1783. Various scenarios of algorithmic collusion have also been examined by competition authorities: see, CMA94, Pricing Algorithms, (October 8th, 2018), available at https://assets.publishing.service.gov.uk/government/uploads/system/uploads/attachment_data/file/746353/Algorithms_econ_report.pdf; Algorithms and Collusion – Note by the European Commission, submitted for the OECD Competition Committee Hearings on 21-23 June 2017, DAF/COMP/WD(2017)12]. Concerns over algorithmic collusion were also raised by the members of the CJEU: See, Opinion of Advocate General Szpunar in Case C 434/15, Asociación Profesional Elite Taxi v Uber Systems Spain SL, ECLI:EU:C:2017:981, fn. 23 (noting that "the use by competitors of the same algorithm to calculate the price is not in itself unlawful, but might give rise to hub and spoke conspiracy concerns when the power of the platform increases"). Some recent economic literature has nevertheless raised questions on the capabilities of algorithms to solve the coordination problem and sustain collusion without some form of communication: see, K-U Kühn and S Tadelis 'Algorithmic Collusion, available at http://www.cresse.info/uploadfiles/2017_sps5_pr2.pdf; U Schwalbe, Algorithms, Machine Learning, and Collusion (June 1, 2018), available at SSRN: <https://ssrn.com/abstract=3232631>

2090

2091 S. Mehra, 'Antitrust and the Robo- Seller: Competition in the Time of Algorithms' (2015) 100 Minnesota L Rev 1323; A Ezrachi and ME Stucke, 'Is Your Digital Assistant Devious?', Competition Policy International (September 2016), available at <https://www.competitionpolicyinternational.com/is-your-digital-assistant-devious/>

The thrust of our argument, accordingly, is that the original question does not lend itself to meaningful resolution through abstract legal reasoning, or economic modeling. These approaches can *inform* our thinking but they cannot provide definitive answers to questions of jurisprudence about collusion and its evidentiary standards when it comes to algorithmic collusion.

This raises interesting questions as to the essence of machine thinking and its conceptualization as a form of cognition. According to one view, the essence of cognition, is the capacity to compute — a capacity attributed to both humans and digital machines. According to a second view, cognition is an inherent property of the human brain. As evidenced by its long and ongoing history, the debate between these essentialist positions is not resolvable for the simple reason that the two sides start with conflicting premises that are not reconcilable. This is an intellectual deadlock that legal scholars should try to avoid.

The language game of antitrust law, which has hitherto involved humans and their firms, now faces the introduction of computers/algorithms as new “players” in the game. The question facing antitrust law is how to deal with this ‘newcomer’. In other words, it should first answer the basic question of whether or not to accept computers as players before it deals with the question of their behavior. This former question has to do with the “constitutive” rules of the game — namely, those that create the game and define it, whereas the latter question has to do with the “normative” rules of the game — namely, which actions are legitimate and which are not²⁰⁹². The game’s constitutive rules take precedence because they determine the conditions of the possibility for the actions performed in the game, just as grammatical rules determine the conditions of possibility for the moves in the language games.

This chapter engages with the economic and technical literature on algorithmic collusion, with the purpose to link it with the broader theory of tacit collusion that has served as the intellectual bedrock of competition law provisions prohibiting cartels and other horizontal collusive practices. We then explore the existing legal framework in order to ascertain if this is adequate to tackle occurrences of algorithmic collusion, or if this has to be re-designed. We focus on the various initiatives of legal form in several BRICS countries and we proceed to a comparison with the approaches followed in the EU and the US. We then move to explore how blockchain technology may impact on the development of collusive strategies and the way these may fall under competition law scrutiny. The last Section examines the emergence of a technical approach in tackling algorithmic collusion, with the development of algorithmic tools by competition authorities, to detect collusion and in particular algorithmic collusion. Competition authorities may thus also employ algorithms to unveil digital cartels, so it is difficult to predict who, competition authorities or colluders, will be one step ahead, from a technology perspective.
